PREFACE

HP ALGOL is similar to the source language defined by the ALGOL 60 Revised Report, Communications of the ACM, January, 1963. The reader should be familiar with ALGOL 60 and with the Hewlett-Packard computer and standard software systems, either through completion of Hewlett-Packard training courses or through equivalent experience. The publication is a programmer's reference manual and is not intended to be used as a training manual.

This edition of HP ALGOL Programmer's Reference Manual supersedes all earlier editions and incorporates all Manual Change Sheets issued to date.

Special features and limitations peculiar to HP ALGOL are described in the Introduction. Section I describes the structure of ALGOL, defining declaration, expressions, and statements. Procedures are described in Section II. Section III covers INPUT/OUTPUT and READ/WRITE operations and the use of FORMAT specifications. Section IV explains the use of the ALGOL compiler; diagnostic messages are also described. Section V describes how to use procedures from FORTRAN or Assembly Language procedures in an ALGOL program.

The HP ALGOL character set and coding examples appear in the Appendices.

Related Programmer's Reference Manuals published by Hewlett-Packard include:

The HP ALGOL compiler is an unsegmented program requiring 8K of memory. In addition to the major elements of ALGOL 60, HP ALGOL has the following features:

- Intermixing of REAL and INTEGER variables on the left-hand side of assignment statements.
- Unrestricted nesting of conditional statements within conditional statements.
- All variables treated as OWN variables.
- Initialization of variables or arrays within type declarations.
- Values assigned to variables with EQUATE declaration.
- Logical unit designation in INPUT/OUTPUT statements.
- HP FORTRAN FORMAT specifications for input/output operations-or for input operations, free field data.
- The ability to reference external procedures or subroutines written in ALGOL, FORTRAN, or Assembly Language.

HARDWARE CONFIGURATION

While the ALGOL compiler will run in a computer with 8192 words of memory using the HP 2752A (ASR-33) or HP 2754A (ASR-35) Teleprinter, the following minimum equipment is recommended:

Main Frame with 16384 words of core storage HP 2737A Punched Tape Reader HP 2753A Tape Punch

The separate tape reader increases the speed of reading source tape. The tape punch enables the user to use the compiler in a one-pass mode, producing a listing and an object tape in the same pass. When only the teleprinter is provided, two passes are required if a listing is specified—one for the binary output and one for the listing.

CHARACTER SET

```
HP ALGOL uses the following basic symbols:
```

Letters A through Z (upper case only)
Digits O through 9
Special Characters

$$+ - * / \uparrow \setminus @ . : " ' ; () [] < > = # , $ blank$$

Note the character differences between ALGOL 60 and HP ALGOL:

ALGOL 60	HP ALGOL		
Letters (upper and lower case)	Only upper-case letters allowed		
x	*		
÷	\ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \		
<u>≤</u>	<=		
<u>></u>	>=		
≠	#		
7	NOT		
^	AND		
V	OR		
≣⊃	(not allowed)		
10	•		
:=	<pre>← or :=</pre>		
٠,	"•••"		

FUNDAMENTALS OF HP ALGOL

The basic symbols defined in the character set are the only symbols recognized by HP ALGOL. These symbols are combined to form identifiers, constants, variables, and specifications; these elements are then combined to form declarations and statements. Declarations and statements are combined into blocks and blocks into a program. Under the syntactic rules of ALGOL, a program can be a single block or several blocks, nested one within another. Similarly, a block can be a single statement or many statements separated by delimiters.

IDENTIFIERS AND RESERVED IDENTIFIERS

An identifier is a name used by the programmer to identify a value, usually a variable. The first character of an identifier must be a letter; the succeding characters may be letters or digits. Spaces may not appear within an identifier. The ALGOL compiler will recognize up to 15 characters; additional characters will be ignored. An identifier must be declared before it is used. (See Section I.)

Certain identifiers have been defined by the system as having specific meanings or functions. These "reserved identifiers" must not be used by the programmer to define his own variables. (See Table I-1.)

Table I-1
Reserved Identifiers

*ABS	END	LABEL	*SIGN	WHILE
AND	ENDFILE	*LN	SPACE	WRITE
*ARCTAN	*ENTIER	NOT	*SQRT	
ARRAY	EQUATE	OR	STEP	
BACKSPACE	*EXP	OUTPUT	SWITCH	
BEGIN	*FALSE	PAUSE	*TAN	
BOOLEAN	FOR	*PI	*TANH	
CASE	FORMAT	PROCEDURE	THEN	
CODE	GO	READ	TO	
COMMENT	IF	REAL	*TRUE	
*cos	INPUT	REWIND	UNLOAD	
DO	INTEGER	*ROTATE	UNTIL	
ELSE	*KEYS	*SIN	VALUE	

*These identifiers have been predeclared, in that the programmer can use them without declaring them. He may, however, override these declarations with his own.

CONSTANTS

The HP ALGOL compiler recognizes four types of constant--decimal, octal, Boolean, and ASCII.

Decimal Constants

A decimal constant consists of the ten digits 0 through 9. If a decimal constant has no decimal point and no scale factor, it is of type INTEGER; a decimal constant with a decimal point and/or a scale factor is of type REAL. Either may have a sign. The apostrophe (') precedes the scale factor.

$$+3.1416'2 = +3.1416 \times 10^2 = +314.16$$

In the examples below, the first two constants are INTEGER; all the rest are REAL:

ALGOL	NUMERIC VALUE
0	0
177	177
.5384	.5384
+0.7300	.7300
-200.084	-200.084
+ 07.43'8	7.43x10 ⁸
9.34'+10	9.43x10 ¹⁰
2'-4	$2x10^{-4}$
083'-02	00083

ASCII Constants

An ASCII constant may contain one or two ASCII characters enclosed in quotation marks and is represented as follows:

[&]quot;A"

If only one character appears between the quotation marks, it is interpreted as a null character followed by the character within quotes.

Octal Constants

An octal integer is represented by the character @ followed by a string of octal digits. No sign is allowed.

Examples: @123

@100

Note that the constants "A", @101, and 65 are all equivalent.

Boolean Constants

There are two Boolean constants -- TRUE and FALSE.

COMMENTS

Comments may be inserted in an ALGOL program for clarity. A comment is indicated either by the word COMMENT or by the ampersand (&).

The word COMMENT may be inserted anywhere in the program; all symbols between the word COMMENT and the next semicolon are treated by the compiler as comments and are printed in the listing, but do not appear in the object code. Comments of this type may be continued for many lines.

The (&) ampersand symbol is used for short comments. All symbols to the right of the ampersand are treated as comments in the line in which the & symbol appears. The next line of the program is treated as normal coding unless the & symbol is repeated. The compiler also ignores these comments when generating object code but prints them on the listing. Following an END symbol, all symbols up to the next END, ELSE, or semicolon are treated as comments.

In the following example the third line, following the symbol BEGIN, and all of the fourth line are comments. The last line is also treated as comments.

```
REAL PROCEDURE INNERPRODUCT (A,B,N);

VALUE N; INTEGER N; ARRAY A, B;

BEGIN COMMENT INNERPRODUCT COMPUTES

SUM FROM I = 1. ..N OF A[I] *B[I];

REAL S; INTEGER I;

S ← 0;

FOR I ← 1 STEP 1 UNTIL N DO S ← A[I] *B[I] +S;

INNERPRODUCT ← S

END OF INNERPRODUCT
```

SECTION I

PROGRAM STRUCTURE

An ALGOL program is made up of two kinds of elements -- declarations and statements. Declarations define the variables used in the program and state their properties. Statements have the character of a command or order.

A program has the form:

The semicolon (;) separates one unit from the next; blank spaces are significant only in certain FORMAT specifications and must not be used in identifiers. Since END is not a statement, no semicolon is necessary after the final statement.

The \$ informs the compiler that this is the end of the program.

DECLARATIONS

Declarations describe the properties of identifiers. HP ALGOL accepts all declarations defined for ALGOL 60 except OWN. (HP ALGOL treats all variables as OWN.) HP ALGOL also accepts an EQUATE declaration.

TYPE

Type declarations declare that certain identifiers represent simple variables of a given type. There are three different types--integer, real, and Boolean. A type declaration consists of the symbol specifying the type, followed by a list of identifiers separated by commas.

EXAMPLES:

INTEGER I, J, K; REAL X, Y, Z; BOOLEAN FLAG;

Dynamic allocation of storage does not occur in HP ALGOL. ALGOL 60 OWN declaration is unnecessary, since all variables are treated as OWN and declared variables are initialized by the compiler. Initialization of a variable is specified by following the variable in the declaration by an assignment symbol and a constant.

EXAMPLES:

INTEGER I, $J \leftarrow 10$, $K \leftarrow 0$; REAL $X \leftarrow 1.5$, $Y \leftarrow -2'5$, Z; BOOLEAN FLAG \leftarrow FALSE;

ARRAY

An ARRAY declaration declares that one or more identifiers represent multidimensional arrays, giving the number of dimensions and the lower and upper bounds of each dimension. The general form is:

```
type ARRAY array name, ..., array name [bounds, ..., bounds], ..., array name [bounds, ..., bounds]
```

EXAMPLES:

REAL ARRAY A [1:100]; INTEGER ARRAY I , J [1:10, 1:10] , K [-50:50]; ARRAY A, B, C [0:10];

An array may be REAL, INTEGER, or BOOLEAN. If no type is given, REAL is assumed.

The subscript bounds for each array are given in the first pair of brackets following the identifier of this array in the form of a bound pair list. Each item of this list gives the lower and upper bounds of a subscript; the two bounds are separated by a colon (:). Since storage allocation is not dynamic, the bounds are restricted to integers. Each lower bound must not be greater than the corresponding upper bound.

An array may have its elements initialized within the declaration. This is accomplished as in the following examples:

DIGITS [I] is initialized to the ASCII equivalent of I, for $I \leq 9$. DIGITS [I] is initially undefined, for I > 9. In a single array declaration, only the last array may be initialized. Other arrays are initialized in other declarations.

LABEL

The LABEL declaration specifies the identifiers of statements to which control may be passed by a GO TO statement.

EXAMPLE:

LABEL AL, L, M1, SAM;

SWITCH

A switch is a set of labels which can be entered as objects of a GO TO statement.

The labels of a SWITCH declaration are associated from left to right with the set of positive integers. When the switch identifier is used as a subscripted expression in a GO TO statement, the label associated with the integer value of the subscript becomes the object of the GO TO statement.

EXAMPLE:

```
LABEL L1, L2, L3, L4;

SWITCH S ← L1, L2, L3, L4;

.:

I+3;

GO TO S[I];
```

Since the value of the subscript is 3, control passes to the statement identified by the label, L3, the third label in the list.

The ALGOL 60 general definition of a switch is not allowed. The labels must all be declared previous to the switch declaration itself. Labels in subblocks of an outer block may not be objects of switches declared in the outer block. When the switch designator is undefined (in the example, when I < O or I > 5), the GO TO statement is equivalent to a dummy statement.

EQUATE

The EQUATE declaration lets the programmer assign values to certain identifiers. The form of the EQUATE declaration is:

EQUATE variable ← constant, ..., variable ← constant

EXAMPLE:

EQUATE
$$N \leftarrow 25$$
, PI $\leftarrow 3.14159$, EPSILON $\leftarrow '-38$;

EQUATE identifiers may be used anywhere in a program where a constant can be used. Identifiers are interpreted the same as the constant to which they are equated.

EXAMPLES:

```
ARRAY A [1:N, 1:N];

AREA ← PI * R * R;

IF X <EPSILON THEN GO TO EXIT;
```

The EQUATE identifier PI is recognized by the compiler without having to be declared; its value is equal to 3.14159.

BLOCKS

Declarations define certain properties of the quantities used in the program, and associate them with identifiers. An ALGOL program is segmented into units called blocks, and a declaration of an identifier is valid for the block in which it appears. The particular identifier may be used outside this block for other purposes.

A block begins with the symbol BEGIN and ends with the symbol END. Following the BEGIN are a number of declarations, then a number of statements, all separated by semicolons:

Since a block is a type of statement, each statement may be a block.

EXAMPLE: BEGIN INTEGER I,J,K; REAL X,Y; S;S; BEGIN INTEGER I; REAL J,L; inner S;S block END; S; S;S END

The identifiers K, X, and Y are declared in the outer block and are valid throughout. Since the inner block is also part of the outer block, K, X, and Y are also valid there. The identifier L is declared for the inner

block only and is meaningless outside it. The identifiers I and J are declared in both outer and inner blocks and may have different definitions in the two blocks. Statements in the inner block which reference I and J refer to the variables declared in the inner block. Statements in the outer block (but not also in the inner block) refer to the variables declared in the outer block.

ARITHMETIC EXPRESSIONS

An arithmetic expression is a rule for computing a numerical value. In simple arithmetic expressions, this value is obtained by executing the indicated arithmetic operations on the values of the quantities involved. The value of a constant is its value; the value of a variable is the last value assigned to it; the value of a function designator is the value arising from the computational rules defining that function procedure.

Operators and Types

Arithmetic expressions must be type REAL or type INTEGER. The meaning of these operators is as follows:

The operators +, -, and * have the standard mathematical meaning (addition, subtraction, and multiplication). The type of an expression is INTEGER if both of the operands are integer, otherwise type is REAL.

The operator / also has the conventional mathematical meaning, but the resultant expression type is always REAL.

The operator \setminus (in ALGOL 60, \div) is defined only for integer operands and results in remainderless division. The value is defined as follows:

 $A \setminus B = SIGN (A/B) * ENTIER (ABS (A/B))$

$$2 \mid 1 = 2$$

 $3 \mid 2 = 1$
 $(-3) \mid (-2) = 1$
 $(-24) \mid 5 = -4$
 $7 \mid 8 = 0$

The value always is of type INTEGER.

The operator MOD may be used to compute the remainder of an integer division. It is defined as follows:

$$A MOD B = A - B * (A \setminus B)$$

EXAMPLES:

$$2 \text{ MOD } 1 = 0$$
 $3 \text{ MOD } 2 = 1$
 $(-3) \text{ MOD } (-2) = -1$
 $(-24) \text{ MOD } 5 = -4$
 $7 \text{ MOD } 8 = 7$

The operator \(\dagger denotes exponentiation, and is defined as follows:

```
a ↑ i (i of type INTEGER):
    if i>0, a * a * ... * a (i times), of the same type as a.
        if i = 0, if a ≠ 0, 1, of the same type as a.
            if a = 0, undefined

    if i<0, if a ≠ 0, 1/(a ↑ (-i)), of type REAL.
            if a = 0, or a of type INTEGER, undefined.

a ↑ r (r of type REAL):
    if a>0, e<sup>r*ln(a)</sup>, of type REAL
    if a = 0,if r>0, 0.0, of type REAL
    if a = 0,if r>0, undefined

if a<0, undefined</pre>
```

The order of operations is determined by the parenthetical structure of the expression. In the absence of parentheses, the operators are executed in the following order:

Operators in the same group are evaluated from left to right.

EXAMPLES:

A + B * C * D / E + F + G value = A +
$$\frac{BxCxD}{(E^F)^G}$$

(A + B) * C + D / E + (F + G) value = (A + B)xC + $\frac{D}{F(F^G)}$

Conditional Expressions

Another type of arithmetic expression has the following form:

This expression is evaluated as follows: if the condition is true, the value of the expression is <expression₁>. If the condition is false, the value is <expression₂>.

Each of the subexpressions may have the IF form.

EXAMPLE:

The value of this expression is minimum {A,B,C}.

The form may be enclosed in parentheses and combined with other expressions.

EXAMPLES:

Note that the value of the two expressions is the same.

VARIABLES

There are three types of operands in arithmetic expressions -- constants, function designators and variables. There are subscripted variables and simple variables, each of which may be of types INTEGER or REAL.

Simple Variables

A simple variable is a single value. This value can be used in arithmetic expressions for forming other values, and is changed by assignment statements. The type of the value of a particular variable is defined in the declaration for the variable itself.

Subscripted Variables

Subscripted variables designate values which are components of multidimensional arrays. A subscripted variable has the form:

<identifier> [<subscript expression> , ... , <subscript expression>]

The number of subscript expressions must be identical to the number of dimensions specified in the array declaration. Each subscript must have an integer value which lies within the boundaries specified for the array in the array declaration.

EXAMPLES:

ASSIGNMENT STATEMENTS

Assignment statements are used to assign the value of an expression to one or more variables or to procedure identifiers. The general form is:

Assignment to a procedure identifier may be made only within the body of a procedure defining the value of a function designator.

EXAMPLES:

$$A \leftarrow B$$
 $A \leftarrow B \leftarrow C + D - E$
 $A \leftarrow B [I, J] \leftarrow C [3, N] - C [K, N + I]$

The variables which precede the assignment symbol (*) are called left part variables. The arithmetic expression following the last assignment symbol is computed and is then assigned to each of the left part variables in turn, from right to left.

Types

In contrast to ALGOL 60, the left part variables need not all be of the same type. If a value of one type is to be assigned to a variable of a different type, the appropriate transfer function is applied.

In the case of a REAL value being assigned to an INTEGER variable, the transfer function has the value

When the types of the left part variables differ, transfer functions are applied from right to left. For example, let X and Y be of type REAL, and I be of type INTEGER. Then the statement:

$$X \leftarrow I \leftarrow Y \leftarrow .3$$

will cause the following assignments to take place:

 $Y \leftarrow .3$

 $I \leftarrow 0$

 $X \leftarrow 0.0$

Note that HP ALGOL uses the symbol "-" instead of the ALGOL 60 symbol ": = ". However, the symbol ": = " will be recognized as being equivalent.

GO TO STATEMENTS

A GO TO statement interrupts the normal sequence of operations, which is the lexical order of statements. The general form is:

GO TO <designational expression>

GO TO defines its successor explicitly by the value of a designational expression. The next statement to be executed will be the one having this value as a label.

EXAMPLES:

GO TO L

GO TO S [I]

Designational Expressions

A designational expression is an expression whose value is a label of a state-

ment. There are two types of designational expressions, labels and switch

designators. The ALGOL 60 IF type of designational expression is not allowed.

<u>Labels</u>

A label is an identifier used to name a statement as one to which control

may be passed by a GO TO statement. More than one label may be used for a

given statement. The general form is:

<label> : <label> : ... : <label> : S

Unsigned integers may not be used as labels.

EXAMPLES:

L: $A \leftarrow X + 1$

L1: L2: G0 T0 S

Every label must appear in a LABEL declaration in the innermost block in

which it appears.

A GO TO statement may not refer to a label in a sub-block of the block in

which the GO TO statement appears. As a result, a block may be entered

only at its head.

CONDITIONAL STATEMENTS

Conditional statements cause certain statements to be executed or skipped

depending upon certain logical conditions.

1-12

There are two general forms:

IF <condition> THEN S_1 ELSE S_2 IF <condition> THEN S

In the first form, if the condition is true, then statement S_1 is executed and S_2 skipped. Otherwise, S_2 is executed and S_1 skipped.

In the second form, if the condition is true, S is executed. If it is false, S is skipped.

EXAMPLES:

IF A < B THEN A \leftarrow B ELSE B \leftarrow A

IF A < B THEN A \leftarrow A + 1

IF A \leftarrow B THEN GO TO L ELSE IF B < C

THEN GO TO M ELSE A \leftarrow B \leftarrow C \leftarrow O

Each of the statements (following either THEN or ELSE) may itself be a conditional statement. If there are fewer ELSEs than IFs, the definition of the conditional statement is ambiguous. This is resolved in HP ALGOL by associating each ELSE with the closest preceding unmatched IF.

For example, the statement

IF A < B THEN IF B < C THEN
$$S_1$$
 ELSE S_2

is interpreted as

IF A < B THEN
$$\{ \hspace{.1cm} \text{IF} \hspace{.2cm} \hspace{.2cm} \text{B} \hspace{.2cm} \text{C} \hspace{.2cm} \text{THEN} \hspace{.2cm} \hspace{.2cm} \text{S}_1 \hspace{.2cm} \text{ELSE} \hspace{.2cm} \text{S}_2 \}$$

rather than as

IF A < B THEN {IF B < C THEN S_1 } ELSE S_2

BOOLEAN EXPRESSION

A Boolean expression is one which has a logical value of TRUE or FALSE. It consists of one or more operands associated with one or more logical operators.

EXAMPLES:

The values of these expressions can be determined from the following table:

B ₁	B ₂	B ₁ OR B ₂	B ₁ AND B ₂	NOT B
TRUE	TRUE	TRUE	TRUE	FALSE
TRUE	FALSE	TRUE	FALSE	FALSE
FALSE	TRUE	TRUE	FALSE	TRUE
FALSE	FALSE	FALSE	FALSE	TRUE

The complete hierarchy of operators is as follows:

Note that the ALGOL 60 operators \supset (implies) and \equiv (equivalent) have been eliminated due to lack of usage.

Boolean Variables

Just as arithmetic values can be assigned to REAL or INTEGER variables, Boolean values can be assigned to variables of type BOOLEAN. For example, if \mathbf{B}_1 and \mathbf{B}_2 are of type BOOLEAN, and Al, A2, and A3 are of type REAL, the following statements are all legitimate:

Boolean variables can also be subscripted, just like arithmetic variables.

EXAMPLE:

B1 [I, J, K]
$$\leftarrow$$
 NOT B1 [I - 1, J - 1, K - 1]

A1 \leftarrow IF B1 [I] THEN A1 \uparrow 2 ELSE IF B1 [I + 1]

THEN A1 \uparrow 3 ELSE 0

To the HP ALGOL compiler, there is no difference between Boolean and integer variables. As a result, Boolean operators and arithmetic operators may be mixed within an expression.

Integer values are considered to be TRUE when they are negative and FALSE when they are positive or zero: thus, only the sign bit (bit 15) is significant with respect to truth or falsity. The operators AND, OR, and NOT act upon all 16 bits, using the machine instructions AND, IOR, and CMA.

The constants TRUE and FALSE are in all ways equivalent to -1 and 0. The two expressions following are different:

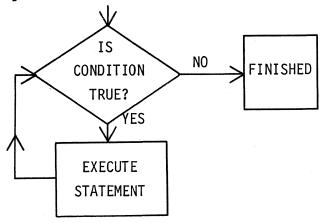

IF <Boolean expression> THEN...
IF< Boolean expression> = TRUE THEN...

WHILE STATEMENTS

The WHILE statement causes repeated execution of a statement as long as a condition exists. The general form is:

WHILE <condition> DO <statement>

When the condition is satisfied, control passes to the next statement in sequence. The processing flow of a WHILE statement is a follows:

EXAMPLE:

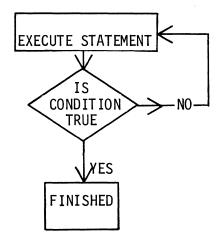

WHILE A < B DO BEGIN A
$$\leftarrow$$
 A + 1; B \leftarrow B - 1 END

Note that the condition is tested before execution, so that if the condition is not TRUE, the statement will not be executed—not even the first time the condition is examined.

DO STATEMENT

The DO statement causes repeated execution of a statement UNTIL a condition becomes TRUE.

DO <statement> UNTIL <Boolean expression>

The statement is executed first, then the Boolean expression is tested. If the expression is FALSE, the statement is reexecuted. If the statement is TRUE, flow continues. Note that the DO statement will be executed at least once whether the expression is TRUE or FALSE.

COMPOUND STATEMENTS

It is often necessary to treat a number of statements as a single logical unit. A typical case is when the execution of the set of statements is subject to a condition. This is easily accomplished in ALGOL by use of the compound statement. A compound statement has the form:

EXAMPLE:

This example is a single conditional statement. First the condition A < B is tested. If it is true, then the statements $A \leftarrow B$ and $B \leftarrow B + 1$ are executed. If it is false, the statements $B \leftarrow A$ and $A \leftarrow A + 1$ are executed.

Since any S can also be a compound statement, they can be nested indefinitely.

EXAMPLE:

This example sets I to one of the following values:

FOR STATEMENTS

The FOR statement allows repeated execution of a statement while performing a sequence of assignments to a "control" variable within the statement. The general form is:

FOR <integer variable> \leftarrow <initial value> STEP <increment> UNTIL <final value> DO <statement>

The variable is assigned the initial value, the statement is executed, the variable incremented, the statement executed again, etc. Execution terminates when the control variable exceeds the final value. The initial value, the increment, and the final value can be any expressions, including negative ones.

The following statement is a simple example. It sets the first n elements of a one-dimensional array to zero:

FOR
$$I \leftarrow 1$$
 STEP 1 UNTIL N DO A [I] $\leftarrow 0$

The effect is to repeat the execution of the statement following the symbol DO (A[I] \leftarrow 0) with the variable I changing its value each time. It takes on the values

This FOR statement is equivalent to:

FOR statements can be nested. The following statement is the two-dimensional analogue of the previous example:

FOR I
$$\leftarrow$$
 1 STEP 1 UNTIL N DO
FOR J \leftarrow 1 STEP 1 UNTIL N DO A[I,J] \leftarrow 0

This is equivalent to:

```
A[N, 1] ← 0;
A[N, 2] ← 0;
. . . .
A[N, N] ← 0;
```

Some examples will serve to illustrate the possibilities of the step-until element.

```
I \leftarrow 1 STEP 1 UNTIL 10 (specifies the values 1, 2, 3, ..., 10)

I \leftarrow 10 STEP -1 UNTIL 1 (specifies the values 10, 9, 8, ..., 2, 1)

I \leftarrow 1 STEP 5 UNTIL 10 specifies the values 1, 6)

I \leftarrow 1 STEP 1 UNTIL N

(If N > 0; the values specified are 1, 2, 3, ..., N.

If N <=0, the FOR list has no values at all.)
```

If the stepping value is 1, the symbols STEP 1 UNTIL may be replaced by the symbol TO. For example,

```
FOR I \leftarrow 1 STEP 1 UNTIL N and FOR I \leftarrow 1 TO N
```

are equivalent.

CASE STATEMENT

The CASE statement causes the execution of one of a number of statements following the CASE statement:

The expression will be evaluated. If its value is between 1 and n, the statement corresponding to that value will be executed. If the value is not between 1 and n, the entire CASE statement is bypassed.

PAUSE STATEMENT

A PAUSE statement causes the word "PAUSE" to be printed on the teleprinter and the computer to be brought to a halt. Program execution resumes when the RUN button is pressed. The PAUSE statement permits the operator to perform some action such as turning on (or off) some device.

SECTION II PROCEDURES

Statements or blocks describing common computational processes may occur several times in the same program, perhaps with different names used to designate some of the quantities involved. Such a process, called a procedure, is often designated and called into execution by a special declaration.

PROCEDURE DECLARATIONS

The PROCEDURE declaration defines a process, as described above. A procedure is subject to the same rules of validity as any declared variable.

(See Section I.)

A procedure contains a procedure body which consists of a single statement, most often a block. Associated with the procedure body is the procedure heading which specifies the parameters to the procedure.

EXAMPLE:

```
Procedure
Heading

PROCEDURE TRANSPOSE (A,N);

VALUE N; INTEGER N; ARRAY A;

BEGIN REAL Z; INTEGER I, J;

FOR I 	1 STEP 1 UNTIL N DO

FOR J 	1 + 1 STEP 1 UNTIL N DO

BEGIN Z 	A[I,J]; A[I,J] 	A[J,I];

A [J,I] 	Z

END

END
```

This sample procedure transposes an $n \times n$ matrix. The procedure heading consists of the following parts:

The reserved word: PROCEDURE

The procedure identifier: TRANSPOSE

The formal parameter part: (A,N); (optional)

The value part: VALUE N; (optional)

The specification part: INTEGER N; ARRAY A; (not required if there

are no formal parameters)

The reserved word PROCEDURE identifies a procedure declaration. The procedure identifier calls the procedure into execution at another place in the program. The formal parameter part gives the names of those identifiers used within the procedure body, but which, when the procedure is called, are replaced by actual parameters whose names may be different. The value part indicates those formal parameters to be called by value. The specification part indicates the types of the formal parameters. In HP ALGOL, all the formal parameters must be specified.

There are no restrictions on the types of formal parameters. Thus, they may be any of the following:

REAL	BOOLEAN ARRAY	LABEL
INTEGER	REAL PROCEDURE	SWITCH
BOOLEAN	INTEGER PROCEDURE	FORMAT
ARRAY	BOOLEAN PROCEDURE	INPUT
REAL ARRAY	PROCEDURE	OUTPUT
THE COLD ADDAM		

INTEGER ARRAY

The procedure body may contain references to any formal parameters, to any local variables (those declared in the procedure body itself, if it is a block), and to any variables declared outside the procedure declaration.

PROCEDURE STATEMENTS

A procedure is called by a PROCEDURE statement.

EXAMPLE:

TRANSPOSE (S,25)
TRANSPOSE (X,25)

This statement calls the procedure which was declared with the name TRANS-POSE. The parameters in parentheses are called actual parameters, and they must correspond in number and type to the formal parameters specified in the PROCEDURE declaration.

Note the correspondence in the example:

FORMAL PARAMETER	ACTUAL PARAMETER	TYPE
А	Х	array
N	25	integer

When the statement TRANSPOSE (X,25) is executed, the elements in the array X are transposed, as follows: if the value of a given element of X, say X[I,J], was Xij before the statement is executed, then after the statement is executed, the value is X[I,J] = Xji. This is accomplished by substituting the array X for A wherever A appears in the procedure body. This substitution is the meaning of a parameter which is called by name, not called by value.

CALL BY NAME/VALUE

Parameters called by value are those whose names appear in the value part of the procedure heading. The main distinction is that formal parameters called by value are computed when the procedure is called and are treated as local variables. Assignments to these parameters have no effect on the value of the actual parameter.

In parameters called by name, the actual parameter is substituted for the formal parameter wherever the latter appears in the procedure body. As a result, any assignments to the formal parameter do affect the value of the actual parameter. When a type parameter is called by name, the actual parameter must be either a simple variable or a subscripted variable.

EXAMPLE:

```
PROCEDURE P1(X); REAL X; X \leftarrow X + 1;

PROCEDURE P2(X); VALUE X; REAL X; X \leftarrow X + 1;

A \leftarrow 0;

P1 (A);

P2 (A);
```

After the procedure Pl is called, the value of A becomes 1.0. It is changed because Pl specifies that the parameter be called by name. If P2 is called next, the value of A is still 1.0 since P2 specifies that its parameter is called by value.

EXAMPLE:

```
INTEGER N, Z;
:
PROCEDURE SAMPLE (M, Y);
VALUE M; INTEGER M, Y;
BEGIN
    INTEGER A;
    A ← M;
    Y ← A + 1
    M ← M + 1
END
N ← 3; Z ← 1;
:
SAMPLE (N, Z) actual parameters
    Result: Z ← N + 1
```

The value of N is unchanged because M was called by value.

Only parameter types REAL, INTEGER, and BOOLEAN may be called by value.

(Arrays are not called by value because storage is not allocated dynamically.)

If an actual parameter is a procedure, then all the parameters of that procedure are called by value.

No procedure may be entered recursively, either implicitly or explicitly.

In a procedure, any variable that is neither a formal parameter nor a local variable must be declared before the procedure declaration.

FUNCTION PROCEDURES

A function procedure is a procedure that results in a single value. This value must be assigned somewhere in the procedure body by an assignment statement with the procedure identifier on the left-hand side.

EXAMPLE:

```
REAL PROCEDURE TRACE (A,N);

VALUE N; INTEGER N; ARRAY A;

BEGIN REAL S; INTEGER I;

S ← O; FOR I ← 1 STEP 1 UNTIL N DO S ←A[I,I] + S;

TRACE ← S

END
```

To specify a function procedure, the word PROCEDURE must be preceded by the type (REAL, INTEGER, or BOOLEAN). A function procedure is called by a PROCEDURE statement or an expression. When a function procedure call appears in an expression, its value is treated as that of a variable of the same type.

CODE PROCEDURES

An ALGOL procedure may be compiled separately from a main program or be written in Assembly Language or FORTRAN. These procedures may be referenced from an ALGOL program by replacing the procedure body with the word CODE. The specifications must all be given.

EXAMPLES:

PROCEDURE INVER (A, X, N);

VALUE N; INTEGER N; REAL A, X; CODE;

REAL PROCEDURE INTEGRAL (A, B, F);

VALUE A, B; REAL A, B: REAL PROCEDURE F; CODE;

A CODE procedure identifier may be a maximum of five characters. If there are more than five characters, only the first five are significant.

INTRINSIC PROCEDURES

Certain identifiers are reserved for the standard functions of analysis, and are referenced as procedures:

NAME	MEANING	TYPE
ABS (E)	absolute value of E	Same as that of E
SIGN (E)	=1 if E>0, 0 if E = 0, -1 if E < 0	Integer
SQRT (E)	√E	Real
SIN (E)	sin E	Real
COS (E)	cos E	Real
ARCTAN (E)	$ an^{-1}$ E	Real
TANH (E)	tanh E	Real
LN (E)	ln E	Real
EXP (E)	e ^E	Real
ENTIER (E)	the largest integer < E	Integer
ROTATE (I)	rotate I 8 bits	Integer
KEYS	16-bit value of switch register	Integer
TAN (E)	tan E	Real

SECTION III INPUT/OUTPUT

HP ALGOL input/output operations involve the following:

```
Input Lists
Output Lists
Formats
READ Statements
WRITE Statements
```

Magnetic Tape Statements

LIST DECLARATIONS

I/O lists specify that variables be read or written by a READ or WRITE statement. The general form of an input or output list declaration is:

Each list identifier refers to a list of elements; each element may be one of the following:

- a. simple variable,
- b. subscripted variable,
- c. list,
- d. expression (only in an OUTPUT list), or
- e. FOR element.

A FOR element is like a FOR statement except that it is followed by either a single list element or a group of list elements. A group of list elements is enclosed in brackets. An input (output) list may call on other input (output) lists. All the elements appearing in a list must be previously declared.

EXAMPLE:

INPUT IN1 (A, B, C, D [I,J], FOR I ← 1 TO L
DO [M[I], N[I]], X),
IN2 (X, Y, Z, IN1);

OUTPUT TRIG(FOR I ← 1 TO L
[I, A[I], SIN(A[I]), COS(A[I])];

FORMAT DECLARATIONS

A FORMAT specification describes the physical arrangement of data. FORMAT specifications must be defined in the declaration part. The general form is:

FORMAT
$$(spec_1, ..., r(spec_n, ...), spec_n, ...),$$
 ...;

More than one format may appear in a FORMAT declaration.

Formats may be declared directly in a READ or WRITE statement, eliminating the need for separate FORMAT statements. See the example of In-Line FORMATS under "READ AND WRITE STATEMENTS" in this section.

FORMAT SPECIFICATIONS

The data elements in the input/output lists may be converted from external to internal and from internal to external representation according to format conversion specifications. If the variable type in the input/output list does not correspond to the type specified in the FORMAT declaration, the compiler converts one type to the other. FORMAT declarations may also contain editing codes.

Conversion Specifications

rEw.d	Real number with exponent
rFw.d	Real number without exponent
rIw	Decimal integer
rAw	Alphanumeric
r@w } rKw }	Octal integer

Editing Specifications

Both W and n are positive integer constants representing the width of the field in the external character string; n may be omitted if the width is one. The symbol d is a non-negative integer constant representing the number of digits in the fractional part of the string. The repeat count, r, is an optional positive integer constant indicating the number of times to repeat the succeeding basic field descriptor. Each h is one character.

Ew.d Output

The E specification converts numbers in storage to character form for output. The field occupies W positions in the output record; the number appears in floating point form right-justified in the field as:

$$\Lambda x_1 \dots x_d^{E\pm ee}$$

The caret symbol, Λ , indicates a space.

 $X_1...X_d$ are the most significant digits of the value of the data to be output, while ee are the digits in the exponent. Field W must be wide enough to contain significant digits, signs, decimal point, E, and exponent. Generally, W should be greater than or equal to d+7.

If the field is not long enough to contain the output value, an attempt is made to adjust the value of d (i.e., truncating part or all of the fraction) so that a number is written in the field. If the remaining value is still too large for the field, dollar signs (\$) are inserted in the entire field. If the field is longer than the output value, the quantity is right-justified with spaces to the left.

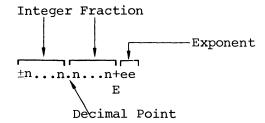

EXAMPLES:

```
FORMAT F5(E10.3);
                         A contains +12.34 or -12.34
                         Result is \Lambda\Lambda. 123E+02 or \Lambda-.123E+02
WRITE(4, F5, A);
FORMAT F5(E12.3);
                         A contains +12.34 or -12.34
                         Result is \Lambda\Lambda\Lambda\Lambda. 123E+02 or \Lambda\Lambda\Lambda-. 123E+02
WRITE(4,F5,A);
FORMAT F5(E7.3);
                         A contains +12.34 or -12.34
                         Result is .12E+02 or -. 1E+02
WRITE(4,F5,A);
FORMAT F5(E5.1);
                         A contains +12.34
                         Result is $$$$$
WRITE(4,F5,A);
```

Ew.d Input

The E specification converts the number in the input field (specified by W) to a real number and stores it in the appropriate storage locations.

The input field may consist of integer, fraction, and exponent subfields:

The integer subfield begins with a + or - sign or a digit and may contain a string of digits terminated by a decimal point, an E, +, -, or the end of the input field.

The fraction subfield begins with a decimal point and may contain a string of digits terminated by an E, +, -, or the end of the input field.

The exponent field may begin with a sign or an E and contains a string of digits. When it begins with E, the + is optional between E and the string. The value of the string of digits should not exceed 38. The number may appear in any position within the field; spaces in the field are ignored.

EXAMPLES:

+1.2345E2

123.456+9

-0.1234-6

.12345E-3

1234

+12345

+1234E6

When no decimal point is present in the input quantity, d acts as a negative power of ten scaling factor. The internal representation of the input quantity will be:

(Integer Subfield) x10^{-d}x10 (Exponent Subfield)

EXAMPLE:

FORMAT F(E12.8);

Input quantity = $\Lambda\Lambda\Lambda1234+5\Lambda\Lambda$

Conversion performed:

1234x10⁻⁸x10⁵

Result:

1.234

If a d value in the specification conflicts with a decimal point appearing in an input field, the actual decimal point takes precedence.

EXAMPLE:

FORMAT F(E12.8);

Input quantity = $\Lambda\Lambda\Lambda\Lambda\Lambda$ 1.234+5

Quantity stored:

1.234x10⁵

The field width specified by w should always be the same as the width of the input field. When it is not, incorrect data may be read, converted and stored. The value of w should include positions for signs, the decimal point, the letter E, as well as the digits of the subfields:

EXAMPLE:

FORMAT F10(E7.2, E5.3, E9.2);

READ(5, $F1\emptyset$,A,B,C);

Assuming input data in contiguous fields:

-12.3E1+1234123.46E-3

 $| \leftarrow E7 \rightarrow | \leftarrow 5 \rightarrow | \leftarrow 9 \rightarrow |$

The fields read would be:

-12.3E1

+1234

123.46E-3

and converted as:

-123. 1.234 .12346

However, if specifications were:

FORMAT F1Ø(E7.2,E4.3,E7.2);

The fields read would be:

-12.3E1 +123 4123.46

and converted as:

-123 .123 4123.46

The effects of possible FORMAT specification errors such as the above may not be detected by the system.

EXAMPLE:

FORMAT Specification	Input <u>Field</u>	Converted <u>Value</u>
E9.2	+1.2345E2	123.45
E9.4	-0.1234-6	0000001234
E4.2	1234	12.34

Fw.d Output

The F specification converts real numbers in storage to character form for output. The field occupies w positions and will appear as a decimal number, right-justified in the field:

The x's are the most significant digits. The number of decimal places to the right of the decimal point is specified by d. If d is zero, no digits appear to the right of the decimal point.

The field must be wide enough to contain the significant digits, sign and decimal point. If the number is positive, the + sign is suppressed. If the field is not long enough to contain the output value, an attempt is made to adjust the value of d (i.e., truncating part or all of the fraction) so that a number is written in the field. If the remaining value is still too large for the field, dollar signs (\$) are inserted in the entire field. If the field is longer than the output value, the number is right-justified with spaces occupying the excess positions on the left.

EXAMPLES:

```
FORMAT F5(F10.3);

: A contains + 12.34 or -12.34

Result: $\lambda \Lambda \L
```

Fw.d Input

The F specification input is identical to the E specification input. Although the fields are generally assumed to contain only a sign, integer, decimal point, and fraction, they may also contain an exponent subfield. All restrictions for Ew.d input apply.

Iw

The Iw specification converts internal values to output character strings or input character strings to internal numbers. The output external field occupies w record positions and appears right-justified as:

$$\Delta x_1 \cdots x_d$$

The x's represent the decimal digits (maximum of 5) of the integer. When the integer is positive on output, the sign is suppressed. If an output field is too short, dollar signs (\$) will be placed in the output record.

The Iw specification, when used for input, is identical to an Fw.0 specification.

EXAMPLES:

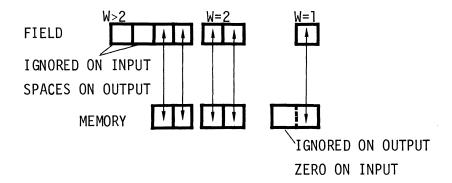

```
FORMAT F10(15, 15, 14, 16);
                                 I contains -1234
                                 J contains +12345
                                 K contains +12345
                                 L contains +12345
WRITE(6,F1\emptyset,I,J,K,L);
Result: -123412345$$$_{\Lambda}12345
        | ← 5 → | ←5 → | ←4 → | ←6 → |
FORMAT F1Ø(I5,I5,I4,I1);
                                 Input contains:
                                 -Λ12312ΛΛ3Λ1Λ23
                                |+5 → | + 5→ | +4→ | |+1
READ(5,F1\emptyset,I,J,K,L);
I contains -0123
J contains 12003
K contains 0102
L contains 3
```

Αw

The Aw specification causes alphanumeric data on an external medium to be translated to or from ASCII form in memory. The associated list element must be of type INTEGER.

On input, if the field indicated by w is greater than 2, the first w-2 characters are ignored; only the last two characters are read. When w equals 2, the two characters are read. If w equals 1, one character is read and stored in the right half of a computer word; zero is entered in the left half.

On output, if the field is greater than 2, two characters are written right-justified in the field; the leading positions are filled with spaces. If w equals 2, the two characters are written. If w equals 1, the character in the right half of the computer word is written.

EXAMPLE:

@w and Kw

Octal integer values are converted under either the @ or the K specification. The field is w octal digits in length; the corresponding list element must be INTEGER.

On input, if w is greater than or equal to 6, up to six octal digits are stored; non-octal digits appearing within the field are ignored. If the value of the octal digits within the field is greater than 177777, the

results are unpredictable. If w is less than 6 or if fewer than six octal digits are encountered in the field, the number is right-justified in the computer word and filled with leading zeros.

On output, if the field is greater than 6, six octal digits are written right-justified in the field; the leading positions are filled with spaces. If w equals 6, the six octal digits are written. If w is less than 6, the w least significant octal digits are written.

EXAMPLE:

Input data: 123456-1234562342342342,396E-Ø5 CR LF INTEGER ARRAY ID[1:2], IE[1,2]; INTEGER IB, IC; FORMAT F10(06, 07, 205, 204);

READ(5,F10,IB,IC,ID[1]; ID[2], IE[1], IE[2]);

Result: IB 123456

IC 123456

ID Ø23423

Ø42342

IE ØØØØ36

ØØØØØ5

<u>n X</u>

The X specification is used to include n blanks in an output record or to skip n characters on input to permit spacing of input/output quantities. In the specifications list, the comma following ΛX is optional. ΛX is interpreted as 1X; 0X is not permitted.

EXAMPLE:

FORMAT FlØ(E8. 3, 5X,F6.2,5X,I4); A contains + 123.4

B contains -12.34

: I contains -123

WRITE(6,FlØ,A,B,I);

Result: A.1234E3 AAAAAA-12.34 AAAAAA-123

Input:

WEIGHT AA10 PRICE AA\$1.98 AATOTAL \$19.80

FORMAT FlØ(8X,I2,1ØX,F4.2,10X,F5.2);

:

READ(5,FlØ,I,A,B);

Result: I contains 10

A contains 1.98

B contains 19.80

$^{nHh}1^{h}2\cdots ^{h}n$

The H specification transfers any combination of eight-bit ASCII characters, including blanks; n is an unsigned integer specifying the number of characters to the right of the H that are to be transmitted. The comma following the H specification is optional. $_{\Lambda}^{\rm H}$ is interpreted as 1H; 0H is not permitted.

On output, the ASCII data in the FORMAT statement is written in the form of comments, titles, and headings.

EXAMPLE:

FORMAT $F10(20H_{\Lambda}THIS_{\Lambda}IS_{\Lambda}AN_{\Lambda}EXAMPLE_{\Lambda})$;

•

WRITE(6,F1Ø);

Result: THIS IS AN EXAMPLE

FORMAT F1Ø(8HWEIGHT_{$\Lambda\Lambda$}12,1Ø_{Λ}PRICE_{$\Lambda\Lambda$}\$_{$\Lambda$}F4.2,1ØH_{$\Lambda\Lambda$}TOTAL_{$\Lambda\Lambda$}\$_{Λ}F5.2);

•

WRITE(6, F10, I, A, B);

I contains 10

A contains 1.98

B contains 19.80

Result: WEIGHT_{$\Lambda\Lambda$}10 PRICE_{$\Lambda\Lambda$} $\$_{\Lambda}$ 1.98_{$\Lambda\Lambda$}TOTAL_{$\Lambda\Lambda$}\$19.80

On input, the data is transmitted from the unit to the FORMAT statement. A subsequent output statement transfers the new data to the output record.

EXAMPLES:

. _ .

READ(5, $F1\emptyset$);

WRITE(6,F10);

Input:

H INPUT ALLOWS VARIABLE HEADERS

Result:

H INPUT ALLOWS VARIABLE HEADERS

This specification also transfers any combination of ASCII characters (except the quotation marks). The number of characters transmitted is the number of positions between the quotation marks; field length is not specified. If r, an optional repeat count, is present, the character string within the quotation marks is repeated that number of times. Commas preceding the initial quotation mark and following the closing quotation are optional.

EXAMPLES:

```
FORMAT FIØ("THIS, IS, ALSO, AN, EXAMPLE");

:
WRITE(6,FIØ);
Result: THIS IS ALSO AN EXAMPLE

FORMAT FIØ(3"ABC");
:
WRITE(6,FIØ);
Result: ABCABCABC
```

On input, the number of characters within the quotation marks is skipped on the input field.

NOTE: If the closing quotation mark is omitted in coding a FORMAT statement of this type, results are unpredictable.

NEW RECORD

A slash terminates the current record and signals the beginning of a new record of formatted data. A slash may occur anywhere in the specifications list and need not be separated from the other list elements by commas.

Several records are skipped by indicating consecutive slashes or by preceding the slash with a repetition factor; r-l records are skipped for r/. On output, the slash is used to skip lines, cards, or tape records; on input, it specifies that control passes to the next record or card.

EXAMPLES:

REPEAT SPECIFICATIONS

Field descriptors (except nH) are repeated by preceding the descriptor with a repeat count, r. If the input/output list warrants, the conversion is interpreted repetitively up to the specified number of times.

A group of field descriptors, including nH, is repeated by enclosing the group in parentheses and preceding the left parenthesis with a group repeat count. If no group repeat count is specified, a value of one is assumed. Grouped field descriptors may not be nested.

EXAMPLES:

```
FORMAT F10(15,15,15);

:

WRITE(4,F10,I,J,K);

can be written as

FORMAT F10(315);

:

WRITE(4,F10,I,J,K);

FORMAT F10(E8.3,5X,F6.2,5X,I4,E8.3,5X,F6.2,5X,I4);

:

WRITE(4,F10,A,B,I,C,D,J);

can be written as

FORMAT F10(2(E8.3,5X,F6.2,5X,I4));

:

WRITE(4,F10,A,B,I,C,D,J);
```

A nested repetition specification would be:

FORMAT F10(E8.3,5X,5(F6.2,5X,I4));

The group F6.2, 5X, I4 would be written five times, and the entire group, once.

FREE FIELD INPUT

Using certain conventions in the input data, an HP ALGOL program can be written without FORMAT statements. Special symbols included with the ASCII input data items direct the formatting:

""	Comments
@	Octal integer
.E+-	Floating point number
+ -	Sign of item
/	Record terminator
space	Data item delimiters

All other ASCII non-numeric characters are treated as spaces (and delimiters). Free field input may be used for numeric data only and is indicated by an asterisk in the READ statement rather than a FORMAT identifier.

Data Item Delimiters

Any contiguous string of numeric and special formatting characters occurring between two commas, a comma and a space, or two spaces, is a data item whose value corresponds to a list element. A string of consecutive spaces is equivalent to one space. Two consecutive commas indicate that no data item is supplied for the corresponding list element; the current value of the list element is unchanged. An initial comma causes the first list element to be skipped.

EXAMPLE:

1) READ(5,*,I,J,K,L); 2) READ(5,*,I,J,K,L);

Input data: 1720, 1966/ Input data: 1266,,1794,2000

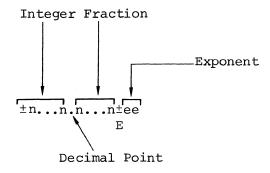

1980 1492

Result: I contains 1720 Result: I contains 1266

J contains 1966
K contains 1980
L contains 1492
J contains 1966
K contains 1794
L contains 2000

Floating Point Input

The symbols for a floating point data item are the same as those used to represent floating point data for FORMAT statement directed input.

If the decimal point is not present, it is assumed to follow the last digit.

EXAMPLES:

READ(5,*,A,B,C,D,E);

Input Data: 3.14, 314E-2, 3140-3, .0314+2, .314E1

All are equivalent to 3.14

Octal Input

An octal input item has the following format:

$$0 x_1 \dots x_d$$

The symbol @ defines an octal integer. The x's are octal digits each in the range of 0 through 7. List elements corresponding to the octal data items are INTEGER.

Record Terminator

A slash within a record causes the next record to be read immediately; the remainder of the current record is skipped.

EXAMPLE:

READ(5,*,II,JJ,KK,LL,MM);

Input data: 987, 654, 321, 123/DESCENDING (CR) (LF)

456

Result: II contains 987

JJ contains 654 KK contains 321 LL contains 123 MM contains 456

<u>List Terminator</u>

If a line terminates ((CR) (LF)) and a slash has not been encountered, the input operation terminates even though all list elements may not have been processed. The current values of remaining elements are unchanged.

EXAMPLES:

READ(5,*,A,B,C,J,X,Y,Z);

Input Data:

A=7.987 B=5E2 C=4.6859E-3

CR) (

(LF

J=3456 (CR) (LF

Result: A contains 7.987

B contains 5E2

C contains 4.6859E-3 J, X, Y, Z are unchanged.

Comments

All characters appearing between a pair of quotation marks in the same line are considered to be comments and are ignored by the compiler.

EXAMPLES:

"6.7321"

is a comment and ignored.

6.7321

is a real number.

READ AND WRITE STATEMENTS

READ and WRITE statements have the following form:

READ (unit, format identifier, input list)

WRITE (unit, format identifier, output list)

The unit is an arithmetic expression with an integer value, which designates an I/O device. The format is the name of some declared format. The absence of the format identifier implies binary I/O. An asterisk (*) instead of a format identifier in a READ statement specifies free field input. The absence of a list means that no variables are to be input or output, but a format specification alone (e.g., nH) may produce input or output.

The input list or output list is a list of elements.

EXAMPLES:

In-Line FORMAT Declarations

The information normally contained in a separate FORMAT declaration may be incorporated into a READ or WRITE statement by using the crosshatch (#) as follows:

may be written

READ (1,#(816,3F7.2),A,B,C)

MAGNETIC TAPE STATEMENTS

Statements are available in HP ALGOL to handle HP magnetic tape operations:

ENDFILE unit
REWIND unit
SPACE unit
BACKSPACE unit
UNLOAD unit

For a complete description, see the *Magnetic Tape System* manual, HP 02116-91752.

UNIT-NUMBER

The integer specified for an input/output unit is a number which represents a unit assignment. The physical device referenced depends on tables established within the control system.

The standard unit numbers for the Basic Control System are as follows:

Number	Name	Usual Equipment Type
1	Keyboard Input	2752A Teleprinter †
2	Teleprinter Output	2752A Teleprinter
3 .	Program Library	2737A Punched Tape Reader
4	Punch Output	2753A Tape Punch
5	Input	2737A Punched Tape Reader
6	List Output	2752A Teleprinter

Installation unit numbers may be in the range 7-74₈ with the largest value being determined by the number of units of equipment available at the installation. Each standard unit may be a separate device, or a single device may be accessed by several standard unit numbers as well as an installation unit number.

(For complete details, see Basic Control System Programmer's Reference manual, HP 02116-9017.)

[†]If data is to be printed on the teleprinter as it is read, unit-reference number 1 must be used; printing occurs with no other number.

SECTION IV USING THE HP ALGOL COMPILER

CONTROL STATEMENT

The first record of any HP ALGOL program must be a control statement. The word HPAL is mandatory. Any combination of the following symbols may appear next, separated by commas:

L: produce source program listing

A: produce object code listing

B: produce object tape

P: a procedure only is to be compiled

S: sense switch control

If no symbols are specified, the program will run but will not produce any output other than diagnostic messages. A program name in quotes (the NAM record name which must be a legitimate identifier with no blanks) may follow.

EXAMPLE:

HPAL,B,P, "INVRT"

If the character "S" is included in the control statement, the B, L, and A options are read by the compiler from the switch register. The switches corresponding to the options:

Switch Control Statement (up) Equivalent	
15	B - produce object tape
14	L - produce source listing
13	A - produce object listing

The switches are read at the beginning of each line so that any option may be "turned off" part way through compilation. Note that the P option, if used, must still be placed in the control statement.

OPERATING INSTRUCTIONS

The following steps indicate the procedure for compilation of a source program:

- a. Set the teleprinter to LINE and check that all equipment to be used is operable.
- b. Load ALGOL compiler using the Basic Binary Loader.†
- c. Turn on punch and list units.
- d. Set Switch Register to starting address of ALGOL (000100).
- e. Press LOAD ADDRESS.
- f. Place source language tape in device serving as the standard input unit (e.g., Punched Tape Reader).
- g. Press RUN. The source listing will be produced on the list unit, and relocatable binary tape on the punch unit. This tape may now be loaded using the BCS Relocating Loader.
- h. If another program is to be compiled, return to Step f.
- i. If the computer prints "HPAL ??", the control statement is incorrect. To restart compilation, place corrected control statement in input unit and press RUN.

DIAGNOSTIC MESSAGES

Errors detected in the source program are indicated by a code number and an "^" below the symbol which caused the error.

Error <u>Code</u>		Description
1	More	than two characters used in an ASCII constant
2	@ not	followed by an octal digit
3	Octal	constant greater than 177777
4	Two o	decimal points in one number
5	Non-i	integer following apostrophe

[†]If Magnetic Tape System is used, set ID number of ALGOL into Switch Register; press PRESET; set Loader switch to ENABLED; and press RUN. (Delete Steps b, d, and e.)

Object Program Diagnostic Messages

During execution of the object program, diagnostic messages are printed on the teleprinter output unit by the I/O system supplied for ALGOL programs. When a halt occurs, the A-Register contains a code which further defines the nature of the error:

Teleprinter Message	A-Register	Explanation	Action
*EQR	Unit Number	Equipment Error: End of input tape on 2752A Teleprinter or 2737A Punched Tape Reader; tape supply low on 2753A Tape Punch. B-Register contains status word of Equipment Table entry.	Place next tape in- put device, or for Tape Punch, load new reel of tape. Press RUN.

USING THE HP ALGOL COMPILER

Teleprinter	_		_
Message	A-Register	Explanation	Action
*FMT	000001	FORMAT error:	Irrecoverable error;
		a) w or d field does not contain proper digits.	program must be recompiled.
		b) No decimal point after w field.	
		c) w-d 4 for E specification.	•
*FMT	000002	a) FORMAT specifica- tions are nested more than one level deep.	<pre>Irrecoverable error; program must be re- compiled.</pre>
		b) A FORMAT statement contains more right parentheses than left parentheses.	
*FMT	000003	a) Illegal character in FORMAT state- ment.	Irrecoverable error; program must be recompiled.
		b) Format repetition factor of zero.	
*FMT	000004	Illegal character in fixed field input item or number not right-justified in field.	Verify data.
*FMT	000005	A number has an ille- gal form (e.g., two E's, two decimal points, two signs etc.)	Verify data.

INDEX? Diagnostic

The INDEX? diagnostic will appear at run time whenever an attempt is made to access an array with an invalid index. After INDEX? is printed, the computer halts and the A-Register contains the address at which the illegal reference was made. If RUN is pushed, the program continues from that point.

USING THE HP ALGOL COMPILER

Library Routine Diagnostics

During the execution of an object program referring to the library routines, the following error codes may be printed on the teleprinter output unit when error conditions are encountered by the specified subroutine: †

Error Code	Subroutine	Condition
03 UN	SQRT	a < 0
04 UN	.RTOR	$x = 0, y \leq 0$
		$x < 0, y \neq 0$
05 OR	SIN, COS	a >2 ¹⁴
06 UN	.RTOI	$x = 0, i \leq 0$
07 OF	EXP	$ a *log_2 e \ge 124$
08 OF	.IOTI.	i ^j out of range
08 UN	.ITOI	$i = 0, j \le 0$
09 OR	TAN	a > 2 ¹⁴

UN = Floating point underflow

OF = Integer or floating point overflow

OR = Out of range

[†] For complete details, see Program Library manual (HP 02116-9032).

SECTION V

FORTRAN AND ASSEMBLER SUBROUTINES

An ALGOL program can refer to procedures that have been prepared using FORTRAN or assembly language; these subroutines are declared CODE procedures. (See Section II.) Object programs generated by the ALGOL or the FORTRAN compiler, or by the Assembler may then be linked by the Basic Control System Relocating Loader when the programs are loaded.

CALLING FORTRAN SUBROUTINES FROM ALGOL

A FORTRAN subroutine is called from an ALGOL program by declaring it a CODE procedure. Since FORTRAN and ALGOL are not fully compatible, the following rule should be obeyed:

If a parameter is an array, the formal parameter must be specified as REAL or INTEGER (depending on the type of array) rather than as ARRAY or INTEGER ARRAY. The actual parameter should be the first element of the array.

EXAMPLE:

```
PROCEDURE F(A); REAL A; CODE;
ARRAY A [1:10];
F(A[1])
```

The following is wrong:

PROCEDURE F(A); ARRAY A; CODE; F(A);

CALLING ALGOL SUBROUTINES FROM FORTRAN

An ALGOL procedure can be called from FORTRAN if it is compiled with the P option in the control statement. Arrays can not be passed as parameters.

CALLING ALGOL PROCEDURES FROM ASSEMBLY LANGUAGE

The calling sequence to an ALGOL procedure from assembly Language is:

<return address>...

The ALGOL call would be:

$$proc (par_1, par_2, ..., par_n)$$

CALLING ASSEMBLY LANGUAGE PROCEDURES FROM ALGOL

Assembly language procedures called from ALGOL either obtain parameters from the calling sequence as given in C, or use the standard ALGOL entry section:

ENT P
EXT .PRAM

NOP

JSB .PRAM

< code words >

< parameters >

JMP P, I

The code words have the following format:

First Code word: bits 15 - 10 = number of parameters

bits 9 - 8 = bit pair for first parameter

bits 7 - 6 = bit pair for 2nd parameter

• • •

bits $1 - \emptyset = bit pair for 5th parameter$

FORTRAN AND ASSEMBLER SUBROUTINES

Second Code Word: bits $15 - 14 = bit pair for 6^{th} parameter$... bits $1 - \emptyset = bit pair for 13^{th} parameter etc.$

A bit pair for a parameter is as follows: the first bit is 1 if the parameter is called by value, \emptyset if it is called by name. The second bit has no significance for name parameters; while for value parameters, it is 1 for real variables and 0 for integer variables.

The locations which follow the code words must contain exactly enough words for the parameters. There are two words for each REAL, VALUE parameter, and one word for every other parameter.

EXAMPLE:

PROCEDURE P(A, B, X, Y); VALUE A, B; INTEGER A, X: REAL B, Y; P NOP JSB . PRAM OCT 11300 A BSS 1 VALUE INTEGER B BSS 2 VALUE REAL X BSS 1 NAME BSS 1 NAME START....

All references to A and B should be direct, since they are values. All references to X and Y should be indirect, since they are addresses.
