INTELLIGENT DISK CONTROLLER (IDC) DISK SYSTEM

Installation and Maintenance Manual

PERKIN-ELMER

The information in this document is subject to change without notice and should not be construed as a commitment by The Perkin-Elmer Corporation. The Perkin-Elmer Corporation assumes no responsibility for any errors that may appear in this document.

The hardware description in this document is intended solely for use in operation, installation, maintenance, or repair of Perkin-Elmer equipment. Use of this document for all other purposes, without prior written approval from Perkin-Elmer is prohibited.

Any approved copy of this manual must include the Perkin-Elmer copyright notice.

Warning: This equipment generates, uses, and can radiate radio frequency energy and if not installed and used in accordance with the instructions manual, may cause interference to radio communications. It has been tested and found to comply with the limits for a Class A computing device pursuant to Subpart J of Part 15 of FCC Rules, which are designed to provide reasonable protection against such interference when operated in a commercial environment. Operation of this equipment in a residential area is likely to cause interference in which case the user at his own expense will be required to take whatever measures may be required to correct the interference.

PREFACE

This manual documents the installation, operation and maintenance of an intelligent disk controller (IDC) disk system. An IDC disk system is a mass storage module (MSM) system or a medium capacity cartridge disk drive (MCCDD) system having as its controller a printed circuit board referred to as the IDC.

Chapters 1 and 2 are directed towards all users, e.g.; sales personnel, instructors, customer engineers, technicians and programmers. Chapter 1 defines what an IDC disk system is. Chapter 2 presents detailed parts lists for possible IDC disk systems and discusses procedures for installing an IDC disk system. Chapters 3 and 4 are directed to customer engineers, technicians and programmers. Chapter 3 describes the operation of the IDC board at the block diagram level. Chapter 4 presents detailed information necessary for the maintenance of an IDC disk system.

This manual is also intended to cover the operation of the high speed intelligent disk controller (HSIDC). All sections are pertinent to the description of operation for the HSIDC with the following exceptions:

- The HSIDC (35-932) is configurable only into systems with the MSM825F disks.
- The HSIDC is designed to operate with shared memory data (SMD) interface devices using up to 15MHz data clocks which allows for disk data transfer rates of up to 1.8MB per second.

Revisions 21 through 23 include text and drawing changes. Schematic and assembly drawings for the HSIDC have been incorporated to accommodate support of the 825MB disk drives.

For information on the contents of all 32-bit manuals, see the 32-Bit Systems User Documentation Summary.

CHAPTER 1
OVERVIEW

1.1 DESCRIPTION OF AN INTELLIGENT DISK CONTROLLER (IDC) DISK SYSTEM

A disk system is the hardware that provides a processor with disk support. It provides a processor with the capability of writing to and reading from disk media. Basically, a disk system consists of these hardware components:

- one or more disk files (a disk file is a disk drive with removable or fixed disk media),
- a controller for interfacing these disk files to the processor, and
- necessary cabling for interconnecting the controller hardware and disk files.

An IDC disk system provides a Series 3200 Processor with support for direct access devices or disk files. Chapter 2 specifies all components of the various IDC disk systems. As shown in Figure 1-1, an IDC disk system consists of:

- one controller board, a printed circuit (PC) board referred to as the IDC,
- one to four disk files with specially formatted disk media, and
- necessary cabling for connecting the IDC and disk files.

Figure 1-2 shows the IDC PC board. This board contains microprocessor logic for directly interfacing disk files with the Series 3200 Processor. Data transfer to and from the processor, via a direct memory access (DMA) port, is through either a Series 3200 selector channel (SELCH) or channel manager (CM). For data recovery from disk read errors, the IDC has the capability of performing strobe offset or track offset sequences. It also has an automatic error correction capability for correcting error bursts of up to 11 bits in length. For detailed programming information on the characteristics of the IDC, see Table 1-1 and the Intelligent Disk Controller (IDC) Programming Manual.

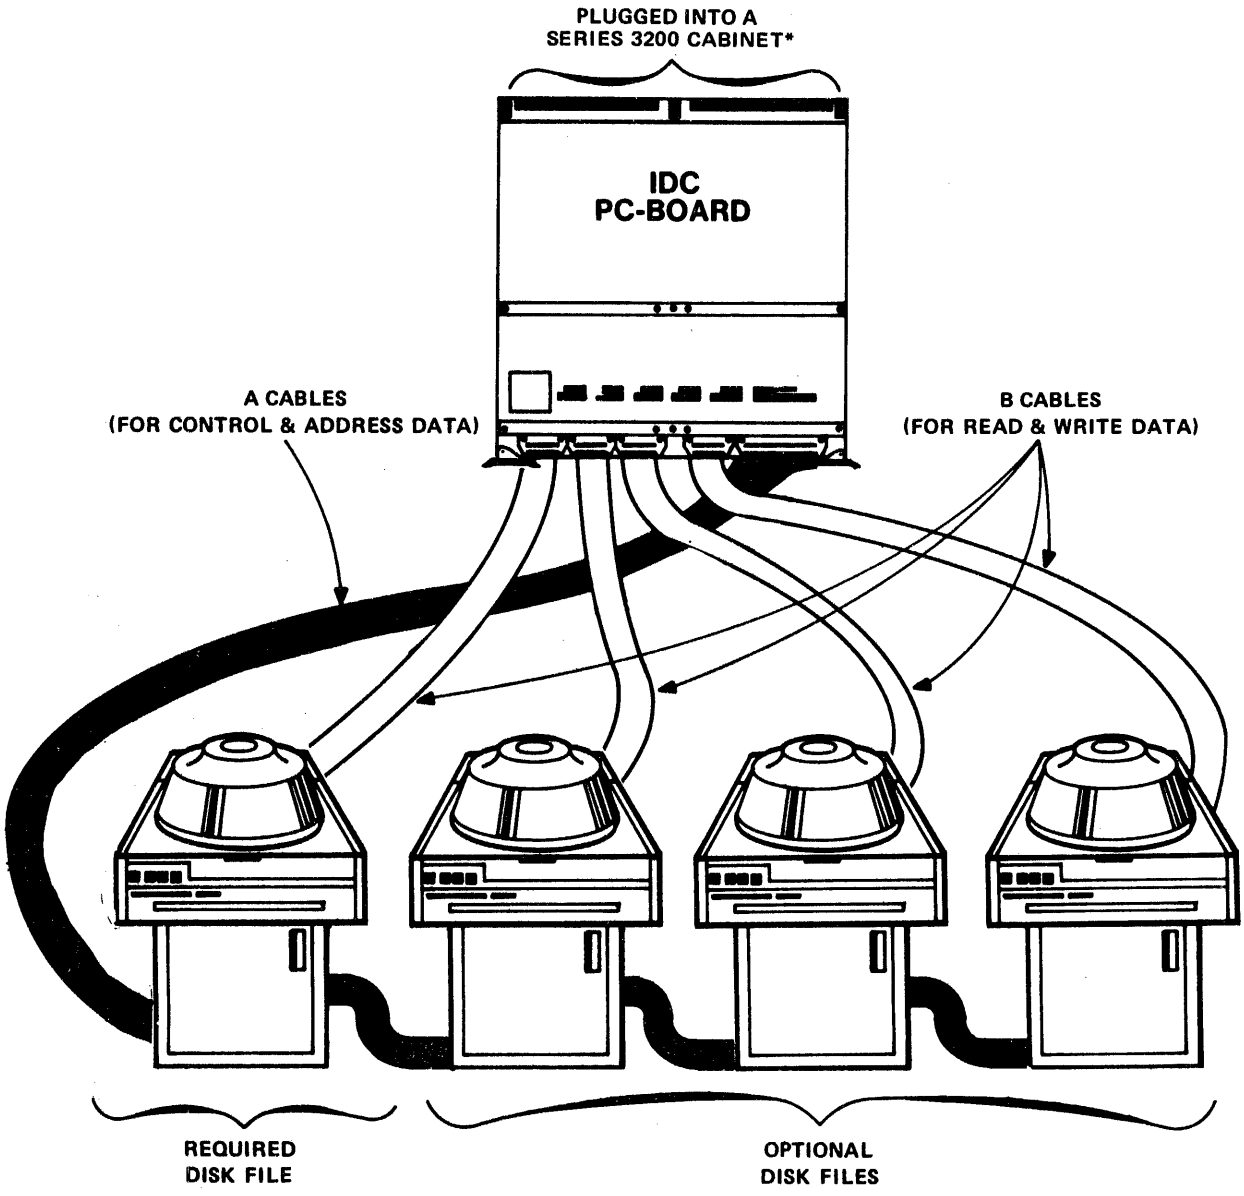
The IDC can interface a maximum of four disk files to the Series 3200 Processor with overlapping seek and restore operations. These can be any combination of disk files, i.e., mass storage modules (MSMs) and/or medium capacity cartridge disk drives (MCCDDs). For example, four interfaced files might be one of the following combinations: 67MB MSM, 256MB MSM, 256MB MSM, and 81MB cartridge disk drive (CDD); or, 256MB MSM, 256MB MSM, 256MB MSM, and 54MB CDD; or, this: 27MB CDD, 54MB CDD, 81MB CDD, and 256MB MSM. The IDC board will also support future disk files. For performance data and other information on the supported disk files, see the vendor manuals listed in Table 1-1.

NOTE

The disk media of an IDC system have a physical format that is different from and incompatible with the format of MSM disk media. For additional information on these differences, see the IDC Programming Manual.

MSM disk drives allow installation of a dual-port option which permits two controllers to share a single disk file; these two controllers can be in the same processor cabinet or in separate processor cabinets. The MCCDD and CDD50 systems are not capable of dual-port operation.

Cabling from the IDC board to the disk files is simple and direct because there is no interface, such as a control panel, between the board and interfaced files.



* For special applications requiring an Input/Output (I/O) bus switch, the IDC is installed in a slot under the I/0 bus Switch.

1.2 LIST OF RELATED PUBLICATIONS

Table 1-1 lists the manuals related to IDC disk systems.

TABLE 1-1 LIST OF RELATED PUBLICATIONS

RELATED MANUAL
M48-018 Input/Output (I/O) Bus Switch Manual and Control Panel Installation Manual
80MB Maintenance Manual Package (This package contains vendor manuals for the 67MB MSM removable media disk systems.)
300MB Maintenance Manual Package (This package contains vendor manuals for the 256MB MSM removable media disk systems.)
Model 3200 Selector Channel (SELCH) Maintenance Manual
80MB (Fixed) Maintenance Manual Package (This package contains vendor manuals for the 67MB MSM fixed media disk systems.)
Vendor Manual Cartridge Disk Drive (This manual is for the 27MB, 54MB and 81MB MCCDD systems.)
825MB (Fixed) Maintenance Manual Package (This package contains vendor manuals for the 646MB MSM fixed media disk systems).
Channel Manager (CM)
Intelligent Disk Controller (IDC) Programming Reference Manual (includes CDD50 system)
330MB Disk Drive Vendor Manual

CHAPTER 2
INSTALLATION

2.1 INTRODUCTION

This chapter gives detailed parts lists and instructions for installing an intelligent disk controller (IDC) system. Before reading it, you should be familiar with Chapter 1.

2.2 DETAILED PARTS LISTS

Tables 2-1 through 2-20 in this section list the components and give a product-number to part number cross reference for the disk systems supported by the IDC. Corresponding to these tables are the 21 IDC disk systems:

TABLE	DISK SYSTEM	DESCRIPTION
2-1	1	Removable Media 67MB MSM Disk System, 60Hz
2-2	2	Removable Media 67MB MSM Disk System, 50Hz
2-3	3	Fixed Media 67MB MSM Disk System, 60Hz
2-4	4	Fixed Media 67MB MSM Disk System, 50Hz
2-5	5	Fixed Media 67MB MSM Disk System, 60Hz, with HPT*
2-6	6	Fixed Media 67MB MSM Disk System, 50Hz, with HPT*
2-7	7	Removable Media 256MB MSM Disk System, 60Hz
2-8	8	Removable Media 256MB MSM Disk System, 50Hz
2-9	9	27MB MCCDD System, 60Hz
2-10	10	27MB MCCDD System, 50Hz
2-11	11	54MB MCCDD System, 60Hz
2-12	12	54MB MCCDD System, 50Hz
2-13	13	81MB MCCDD System, 60Hz
2-14	14	81MB MCCDD System, 50Hz
2-15	15	Fixed Media 330MB Disk System, 60Hz
2-16	16	Fixed Media 330MB Disk System, 50Hz
2-17	17	CDD50 Disk System, 60Hz
2-18	18	CDD50 Disk System, 50Hz
2-19	19	Fixed Media 825MB MSM Disk System, 60Hz+
2-20	20	Fixed Media 825MB MSM Disk System, 220V/50Hz+
2-20	21	Fixed Media 825MB MSM Disk System, 240V/50Hz+

* HPT refers to the Head Per Track option available with the 67MB fixed media disk.

+ Applies only to systems with HSIDC

See Section 2.2.1 for additional cabling information.

2.2.1 Additional Cabling Information

Table 2-21 is a summary of all the cables and straps associated with the IDC disk systems. As listed in the table, those cables and straps having a functional variation with the part number are applicable to your particular system. For example, instead of installing the 15ft A-cable numbered 17-521F01, you can select the 8ft A-cable numbered 17-521F02.

TABLE 2-21 STANDARD CABLING SUPPLIED WITH IDC DISK SYSTEMS

PART NO.	CABLE/STRAP	DESCRIPTION
17-685	External A-Cable and B-Cable	Shielded, 9.14m (30ft), for first drive of all removable media systems.
17-685F01	External A-Cable and B-Cable	Shielded, 4.57m (15ft), for first drive of all MCCDD systems.
17-686	External B-Cable	Shielded, 9.14m (30ft), for second third, and fourth drives of all removable media disk systems.
17-686F01	External B-Cable	Shielded, 4.57m (15ft), for second third, and fourth drives of all MCCDD systems.
17-687	External A-Cable	Shielded, 4.57m (15ft), for second third and fourth drives of all removable media disk systems.
17-520F01	External B-Cable	Heavy duty, shielded, 4.57m (15ft), for all drives of fixed media 67MB systems.
17-521F01	External A-Cable	Heavy duty, shielded, 4.57m (15ft), for first drive of fixed media 67MB systems.
17-521F02	External A-Cable	Heavy duty, shielded, 2.44m (8ft), for second, third and fourth drives of fixed media 67MB systems.
17-411F03 M01	External A-Cable	Heavy duty, shielded, 1.07m (42in), for second, third and fourth drives of MCCDD systems.
17-663	External A-Cable and B-Cable	Shielded, 1.52m (5ft), for first drive of CDD50 systems.
17-664	External A-Cable	Shielded, 1.07m (3.5ft), for all drives of CDD50 systems.
17-665	External B-Cable	Shielded, 1.52m (5ft), for all drives of CDD50 systems.
17-295F01	Ground Strap	9.14m (30ft)
17-295F03	Ground Strap	4.57m (15ft)
17-295F04	Ground Strap	1.83m (6ft)
17-295F05	Ground Strap	1.07m (42in)

2.3 UNPACKING INSTRUCTIONS

For instructions on how to unpack your particular IDC disk system, see the supplied vendor manuals. These manuals are listed in Table 1-1 and in the tables of Section 2.2.

2.4 INSTALLING AN INTELLIGENT DISK CONLROLLER (IDC) DISK SYSTEM

Figure 2-1 is a general illustration of how to install a normal IDC disk system. A normal IDC disk system is one which has the IDC board plugged into the processor cabinet and employs the normal selector channel (SELCH) protocol. IDC (35-807) revision level 10 and above must have its backpanel pin 224-1 wired to its SELCH backpanel pin 224-1. If the IDC board for your system is installed with an input/output (I/O) bus switch, and consequently employs the "new" high-speed SELCH protocol, then your system is not normal. Its installation requires the additional information presented in the M48-018 I/O Bus Switch Manual and Control Panel Installation Manual.

Along with the applicable vendor manuals listed in Table 1-1 and the relevant tables in Section 2.2, Figure 2-1 should enable you to install your particular IDC disk system. However, before plugging in your IDC board and connecting the cables as shown in the figure, you must set two address switches; see Section 2.4.1. For optional IDC board strapping, see Section 2.4.2.

See Section 2.5 if one or more of your disk drives are to be equipped with a dual-port option.

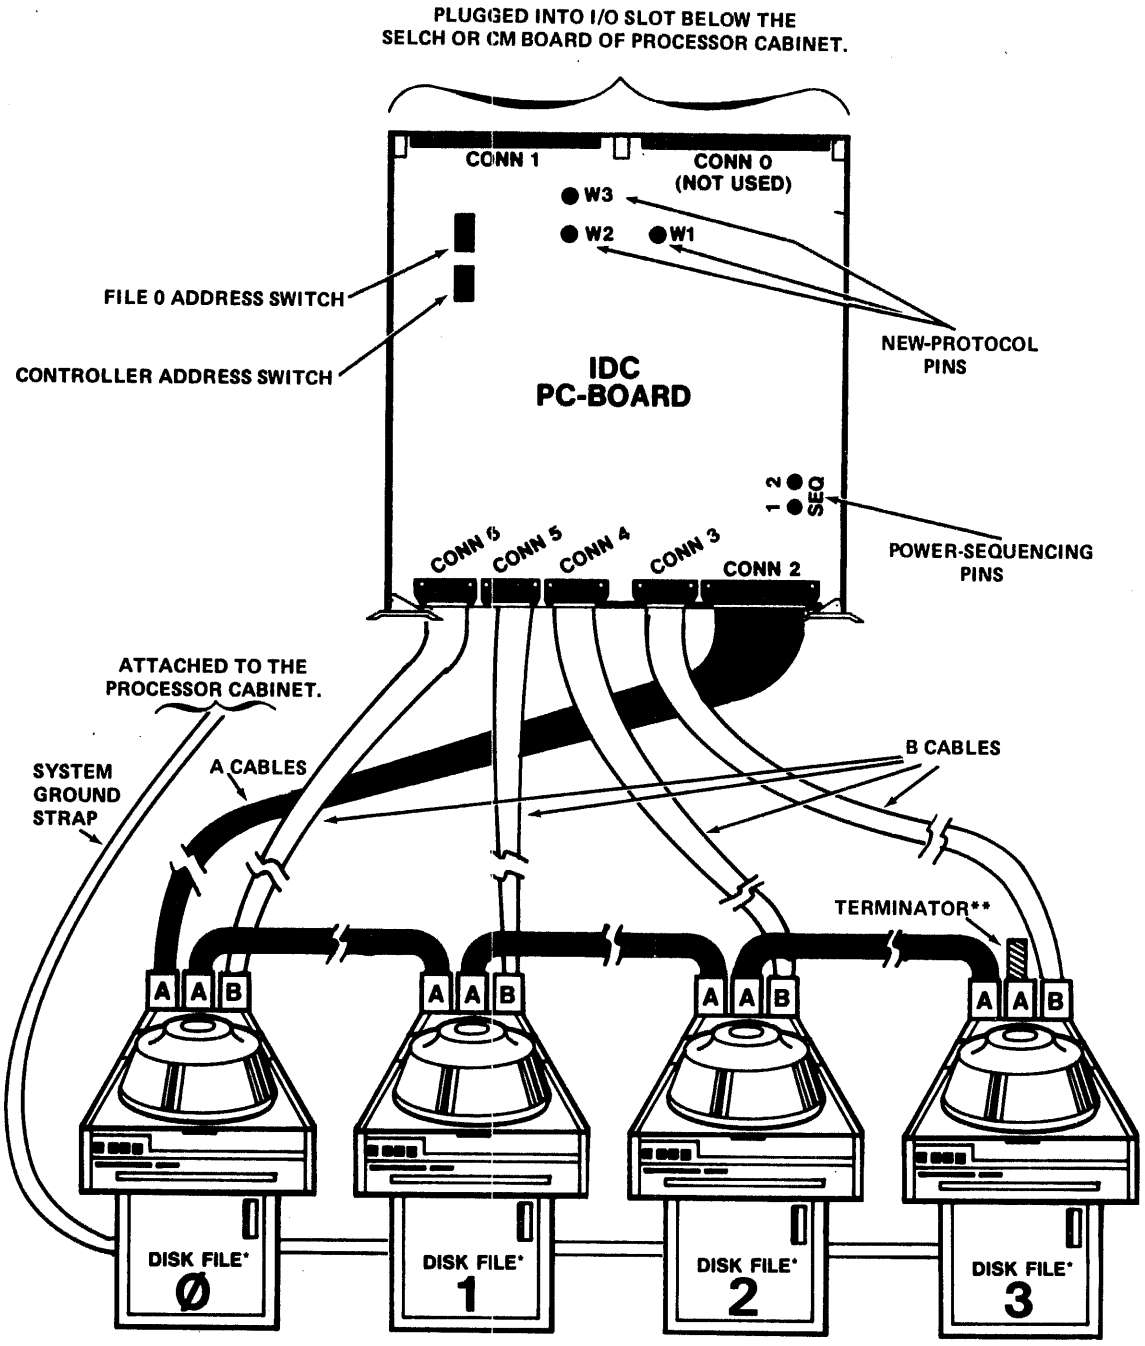
2.4.1 Setting the Address Switches on the Intelligent Disk Control (IDC) Board

As seen from Figures 1-2 and 2-1, the IDC board has two address switches in its upper-left corner:

1. Controller address switch (or device address switch)
2. File 0 address switch

Figures 2-2 and 2-3 present a close up view of these switches. As shown in Figure 2-2, the controller address switch has eight toggles, numbered 1 through 8, each with two possible settings: 0 or 1. Each toggle setting represents a bit in a 1-byte controller address, with toggle 1 being the most significant bit (MSB) and toggle 8 being the least significant bit (LSB). You must set the toggles to the address wanted for your IDC.

As shown in Figure 2-3, the file 0 address switch also has eight toggles, numbered 1 through 8, each with two possible settings: 0 or 1. Toggles 1 through 6 represent six bits in a 1-byte address for your disk file 0, with toggle 1 being the MSB. The other two bits of the 1-byte address are always considered as zero. Toggles 7 and 8, which will be discussed shortly, are for selecting the new high-speed SELCH protocol and for enabling or disabling IDC formatting capability. They are not used for addressing.



* Connector numbers depend on the disk files configured.
** Last disk drive must have a terminator, as shown with the A-cable plug.

Figure 2-1 Installation of an IDC Disk System

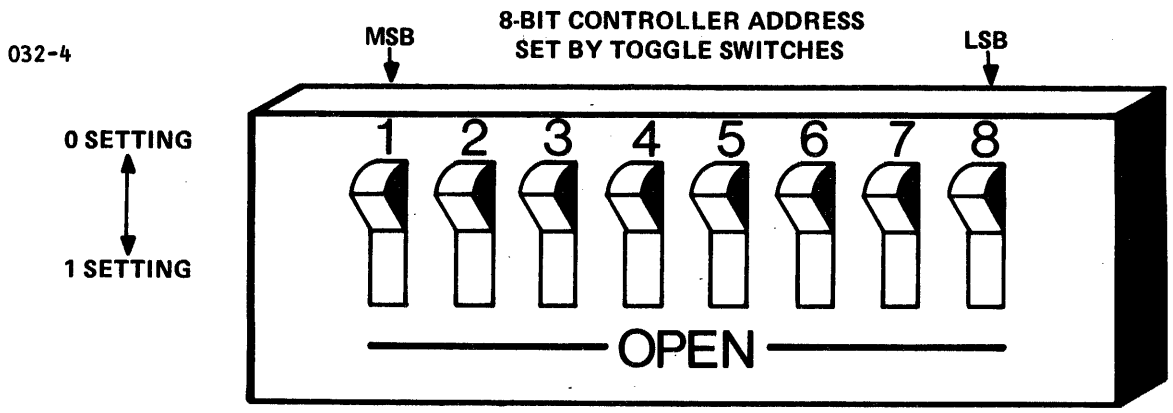


Figure 2-2 Controller Address Switch

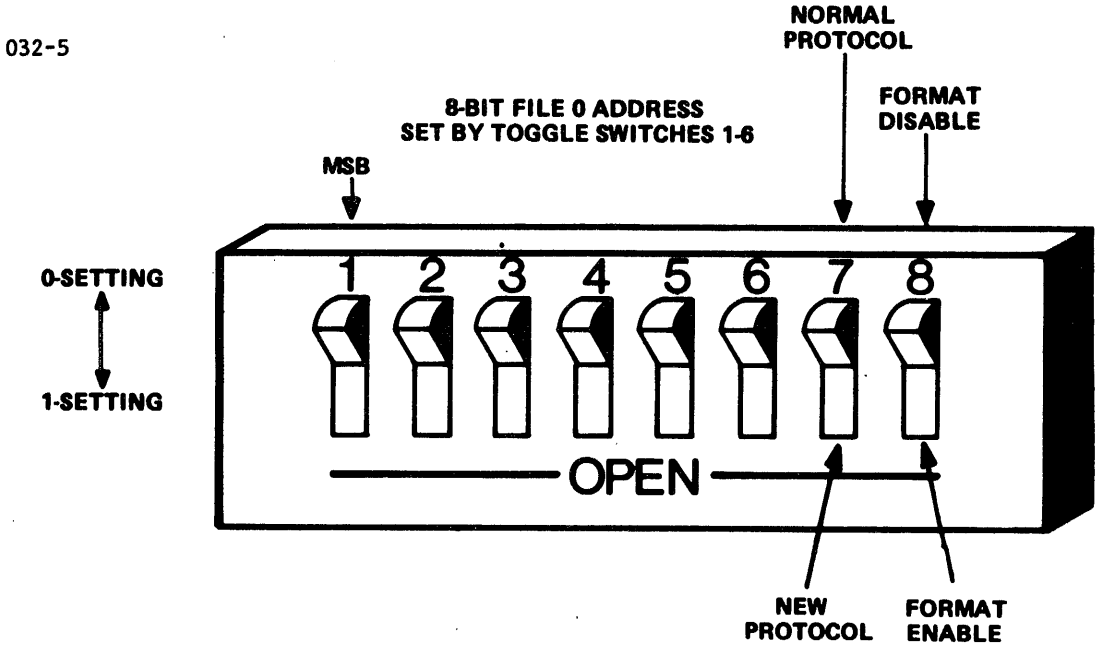

Figure 2-3 File 0 Address Switch

As an example for setting addresses on these switches, suppose you have an IDC system consisting of one IDC board and four disk files. You want the controller address to be X'FB' and the four disk file addresses to be X'FC' through X'FF'. Before installing the IDC board, you would set the controller address switch to the binary value of '11111011' (for X'FB') and the file 0 address switch to '11111100' (for X'FC'). Disk files 1 through 3 are automatically addressed at X'FD', X'FE' and X'FF', respectively.

Now, with the desired addresses set on the two switches, you have the option of setting toggle 7 and/or toggle 8 in the file 0 address switch. If you want to employ the normal SELCH protocol, you push toggle 7 up to the 0 setting. But if your IDC is plugged into the 25ft cable of an I/O Bus Switch, you must push toggle 7 down to the 1 setting, thereby employing the new high-speed SELCH protocol. For additional information on the I/O bus switch, see the M48-018 I/O Bus Switch Manual and Control Panel Installation Manual. (Also, as discussed in Section 2.4.2, the new protocol pins W1 and W3 should be strapped when toggle 7 is at the 1 setting.) In summary, place toggle 7 in the 0 setting when your IDC board is plugged into the processor cabinet; place toggle 7 in the 1 position when your IDC board is plugged into the I/O bus switch.

Toggle 8 of the file 0 address switch is usually left in the 1 setting to enable IDC formatting. That is, if you want the capability of formatting an unformatted disk according to IDC format, leave toggle 8 down. The IDC Programming Manual describes the IDC disk media format in detail. If, for some reason, you want to disable the IDC formatting capability, push toggle 8 up to the 0 position.

2.4.2 Intelligent Disk Controller (IDC) Strapping Information

As shown in Figures 2-1 and 1-2, the IDC board has two sets of pins:

1. Power sequencing (SEQ) pins 1 and 2

2. New protocol pins W1 through W3

Power sequencing refers to the serial application of power to the disk files once the processor is turned on, where: after disk file 0 is powered and comes up to speed, disk file 1 is powered up; after disk file 1 comes up to speed, disk file 2 is powered up; and so forth. When you want your disk files to power up sequentially, do not place a jumper wire across the power sequencing (SEQ) pins 1 and 2. Also ensure that the local/remote switch on each attached disk file is in the remote position. Subsequently, when the processor is turned off, the disk files power down simultaneously. When pins 1 and 2 are strapped, or when the local/remote switch on each attached disk file is in the local position, the disk files can be simultaneously powered up, in parallel, as opposed to serial. Occasionally, simultaneous application of power to the disk files causes an excessive power surge. To determine the advisability of power sequencing to prevent this, see the AC power requirements presented in Section 2.6. The 50MB cartridge disk drive (CDD50), when configured with the IDC, does not use power sequencing, even though it will be passed along to any subsequent drives if enabled on the IDC.

The new protocol pins W1, W2 and W3 apply to the use of the new high-speed SELCH protocol for special applications. The HSIDC board must be strapped for high-speed SELCH protocol with the MSM825F disk drive. When your IDC is installed under an I/O bus switch, and when toggle 7 of the file 0 address switch is down in the 1 setting, you must strap pins W1 and W3. Also, although not recommended, pins W1 and W2 can alternately be strapped for employing the high-speed protocol without the use of an I/O bus switch. This is required when configuring the IDC in a processor which uses the 35-864 CPU board. The MSM825F requires a Series 3200 SELCH. When the IDC board is strapped for high-speed SELCH protocol, backpanel pins 124-1, 224-1 and 225-1 must be wired between the slots containing the IDC and the SELCH.

NOTE

Regardless of the IDC strapping, normal protocol or high-speed, the SELCH used must be strapped for high-speed protocol (see the appropriate SELCH reference manual) and backpanel pin 224-1 of the SELCH slot must be strapped to pin 224-1 of the IDC slot.

2.5 INSTALLING DUAL-PORT OPTIONS

Only the 67MB and 256MB removable media disk systems can be equipped for dual-port operation. Hardware for the dual-port option consists of four items:

1. IDC board
2. Dual-port kit
3. A-cable and B-cable
4. Disk-drive terminator

Sections 2.5.1 through 2.5.4 discuss the installation of these items.

2.5.1 Intelligent Disk Controller (IDC) Board

The additional IDC board supplied with the dual-port option can be plugged into the same processor cabinet with the other controller, or it can be plugged into another processor cabinet. To install the controller in the same cabinet, plug it into the first available backpanel I/O slot below the other controller after removing the RACK0/TACK0 wire from that backpanel. To install the controller into another cabinet, plug it into the first available I/O slot immediately below the SELCH or channel manager (CM) board.

2.5.2 Dual-Port Kit

The dual-port kit consists of these components: driver/receiver printed circuit (PC) boards add-on connectors for the disk file and a dual-port steering card.

After installing the two PC boards and the add-on connectors to the disk drive according to supplied instructions, install the dual-port steering card. First, set three switches on this card according to the operational requirements. Figure 2-4 and Table 2-22 describe and illustrate these switches and associated indicator lights.

2.5.3 A-Cable and B-Cable

A- and B-cable connections depend on whether you are installing just one dual-port option or more than one. Cable connections for a single dual-port disk file are similar to those shown for disk file 0 in Figure 2-1, with one exception: instead of plugging the cables into the plugs labeled A and B in the figure, plug them into the corresponding A and B add-on connectors. On a second, third or fourth dual-ported drive, the A-cable connects to a previously dual-ported drive. With the exception just mentioned, Figure 2-1 also illustrates cable connections for a completely dual-ported IDC disk system.

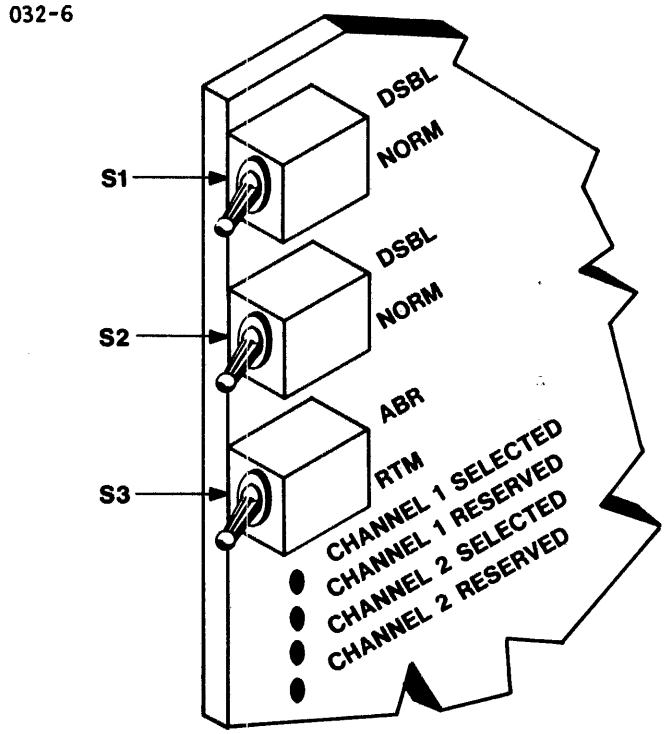

Figure 2-4 Switches and Indicators on Dual-Port Steering Card

TABLE 2-22 SWITCHES AND INDICATORS ON DUAL-PORT STEERING CARD

SWITCHES/INDICATORS	FUNCTION
S1, Maintenance Unit-Disable Switch for Channel 1	This switch has two positions: normal (NORM) and disable (DSBL). It lets you disable channel 1 in the disk drive; i.e., it allows you to disable all transmissions from the disk drive to the controller connected to channel 1. For dual-port operation, S1 should be set to the NORM position, along with S2. During maintenance, S1 should be set to the DSBL position, along with S2.
S2, Maintenance Unit-Disable Switch for Channel 2	This switch has two positions NORM and DSBL. It lets you disable channel 2 in the disk drive; i.e., it allows you to disable all transmissions from the disk drive to the controller connected to channel 2. For dual-port operation, S2 should be set to the NORM position, along with S1. During maintenance, S2 should be set to the DSBL position, along with S1.
S3, Release Timer Select Switch	This switch has two positions: reserve timer (RTM) and absolute reserve (ABR). If you set S3 to RTM, the controller at either channel has about 5 seconds to use the disk file after selecting it. If the controller does not use the file within 5 seconds, it becomes available to the controller at the other channel. If you set the switch to ABR, the controller at either channel has exclusive, uninterruptible use of a disk file; i.e., the controller continues uninterrupted use of that disk file until it issues a release command.
Channel 1 Selected Indicator	Lights to indicate that the channel 1 controller has selected the drive in RTM mode.
Channel 1 Reserved Indicator	Lights to indicate that the channel 1 controller has reserved the drive in ABR mode.
Channel 2 Selected Indicator	Lights to indicate that the channel 2 controller has selected the drive in RTM mode.
Channel 2 Reserved Indicator	Lights to indicate that the channel 2 controller has reserved the drive in ABR mode.

2.5.4 Disk-Drive Terminator

As with single-port disk drives, the last dual-port disk drive attached to the IDC board must have a terminator plugged into the add-on connector of its A-cable plug.

2.6 AC POWER REQUIREMENTS

Table 2-23 lists power requirements for the disk drives supported by IDC.

TABLE 2-23 AC VOLTAGE AND CURRENT REQUIREMENTS FOR DISK FILES*

DISK DRIVES (PART NOS)	INPUT VOLTS	CURRENT REQUIREMENTS	
		STARTING CURRENT	RUNNING CURRENT
27-081F04	115V 60Hz	30A for 15 seconds	8.9A maximum
27-081F05	220V 50Hz	23A for 15 seconds	4.6A maximum
27-115F05	115V 60Hz	23A for 7 seconds	4.7A maximum
27-115F06	220V 50Hz	14A for 7 seconds	2.7A maximum
27-115F07	115V 60Hz	23A for 7 seconds	4.7A maximum
27-115F08	220V 50Hz	14A for 7 seconds	2.7A maximum
27-082F04	115V 60Hz	38A for 10 seconds	8.6A maximum
27-082F05	220V 50Hz	41A for 7 seconds	9.2A maximum
27-131F03	115V 60Hz	23A for 7 seconds	5.0A maximum
27-131F04	220V 50Hz	13A for 7 seconds	2.7A maximum
27-130F03	115V 60Hz	23A for 7 seconds	5.0A maximum
27-130F04	220V 50Hz	13A for 7 seconds	2.7A maximum
27-129F03	115V 60Hz	23A for 7 seconds	5.0A maximum
27-129F04	220V 50Hz	13A for 7 seconds	2.7A maximum
27-148F01	115V 60Hz	20A for 10 seconds	5.0A maximum
27-148F02	230V 50Hz	12A for 10 seconds	3.0A maximum
27-149F01	115V 60Hz	2.1A for 20 seconds	1.2A maximum
27-149F02	230V 50Hz	1.0A for 20 seconds	0.8A maximum
27-178F01+	115V 60Hz	28A for 8 seconds	4.2A maximum
27-178F02+	220V 50Hz	16.5A for 8 seconds	2.1A maximum
27-178F03+	240V 50Hz	15.0A for 8 seconds	2.2A maximum

* See Tables 2-1 through 2-20 in Section 2.2 for more information on these disk files supported by IDC.

\+ Applies only to systems with HSIDC

2.7 APPLICATION OF AC POWER

Depending on how you strap the SEQ pins 1 and 2 on the IDC board, you can apply power to the disk drives either simultaneously (in parallel) or sequentially (in serial). Section 2.7.1 describes simultaneous application of power, where the SEQ pins are strapped or the local/remote switch of each disk file is in the local position. Section 2.7.2 describes sequential application of power, also referred to as power sequencing, where the SEQ pins are not strapped and the local/remote switch of each disk file is in the remote position.

2.7.1 Simultaneous Application of Power

To apply power simultaneously to the disk files attached to your controller(s), follow this procedure:

1. Ensure correctness of all AC power-input connections.
2. At the front of each disk file, depress the START/STOP switch so it is unlit, i.e.; so it is in the STOP position. (This step applies only to the removable-media disk systems.)
3. At the rear of each disk file, set the AC input power switch to the OFF position.
4. Apply primary AC power.
5. At disk file 0, the first drive in the IDC system, set the AC input power switch to the ON position. (At this time, a fixed media disk would start up.)
6. Depress the START/STOP switch so it is lit, i.e.; so it is in the START position. This disk file should now start up; the disk media rotation should come up to speed. If the disk file does not start up, make these additional checks:
   a. Ensure that the remote/local switch in the disk drive is set to the local position.
   b. Check AC input power.
   c. Check fuses in the disk drive.
7. Repeat Steps 5 and 6 for remaining disk files. Consequently, the IDC disk files simultaneously come up to speed.

2.7.2 Power Sequencing

To apply power serially to the disk files attached to your controller(s), follow this procedure:

1. Ensure correctness of all AC power input connections.

2. In each disk drive, set the remote/local switch to the remote position.

3. Apply primary AC power.

4. At the rear of each disk file, ensure that the AC input power switch is in the ON position.

5. At the front of each disk file, depress the START/STOP switch to the START position. (This step applies only to removable media disk files.)

6. Power up the processor in which the controller is connected. The disk files now start up sequentially, starting with disk file 0.

2.8 INTELLIGENT DISK CONTROLLER (IDC) TESTING AND FORMATTING

Once your IDC system is installed and powered up, you can run the IDC Test Program to check for proper operation of your system. Follow this procedure:

1. Ensure you have an IDC formatted media on your disk drive. If you do not, your disk must be formatted by loading and running the IDC Format Program. This program and appropriate instructions are supplied with your IDC disk system.

2. Load and run the IDC Test Program. This program and appropriate instructions are supplied with your IDC disk system.

C A U T I O N

OPTIMUM PERFORMANCE OF AN IDC DISK SYSTEM REQUIRES PROPERLY CERTIFIED DISK MEDIA. TO MINIMIZE THE EFFECTS OF LATENT DEFECTS, REMOVABLE DISK MEDIA HAVE BEEN CAREFULLY SCREENED AND CERTIFIED ON A CALIBRATED DISK DRIVE. THIS CERTIFICATION ASSURES TRANSPORTABILITY OF DISK MEDIA AND MINIMIZES THE OCCURRENCE OF DATA ERRORS.

THE 67MB MSM, 256MB MSM AND MEDIUM CAPACITY CARTRIDGE DISK DRIVE (MCCDD) DISK MEDIA (AVAILABLE ONLY FROM PERKIN-ELMER) ARE RECOMMENDED FOR THE HIGH-PERFORMANCE IDC DISK SYSTEMS.

COMPATIBLE DISK MEDIA MAY BE OBTAINED FROM A VENDOR AND CERTIFIED WITH THE IDC FORMAT PROGRAM, WITH ITS PARAMETERS SET UP EXACTLY AS SPECIFIED WITH THE SUPPLIED INSTRUCTIONS. HOWEVER, THE USER IS CAUTIONED THAT THESE MEDIA MAY RESULT IN REDUCED SYSTEM PERFORMANCE. SPECIFICALLY, DATA MAY NOT BE RECOVERABLE FROM THE MEDIA WHEN IT IS TRANSPORTED BETWEEN DRIVES. SUCH IRRECOVERABLE DATA COULD ALSO RESULT IN AN OPERATING SYSTEM CRASH. IN COMPARISON, A DISK DRIVE, DURING CERTIFICATION, CAN FLAG CERTAIN MEDIA DEFECTS THAT WOULD CAUSE A CRASH.

CHAPTER 3
THEORY OF OPERATION

3.1 BLACKBOX OVERVIEW OF INTELLIGENT DISK CONTROLLER (IDC) BOARD

By understanding the flow of external input/output (I/O) signals associated with the IDC board, you will gain a general idea of what the IDC does. With this objective in mind, this section treats the IDC as a blackbox circuit and presents an overview of all the I/O lines to and from the IDC connectors. Later sections discuss the internal operation of the IDC.

Figure 2-1 illustrates the physical connections of an IDC board. Figure 3-1 illustrates the I/O lines associated with the physical connectors, connector 1 (CONN1) through CONN6, of the IDC board. The following sections briefly describe these I/O lines. Section 3.1.1 describes the lines from IDC CONN1 to the selector channel (SELCH) or channel manger (CM) board plugged into the processor. Section 3.1.2 describes the A-cable lines between IDC connector CONN2 and the attached disk files. Section 3.1.3 describes the B-cable lines between IDC connectors CONN3 through CONN6 and the attached disk files.

NOTE

References in this chapter to the SELCH also apply to the CM.

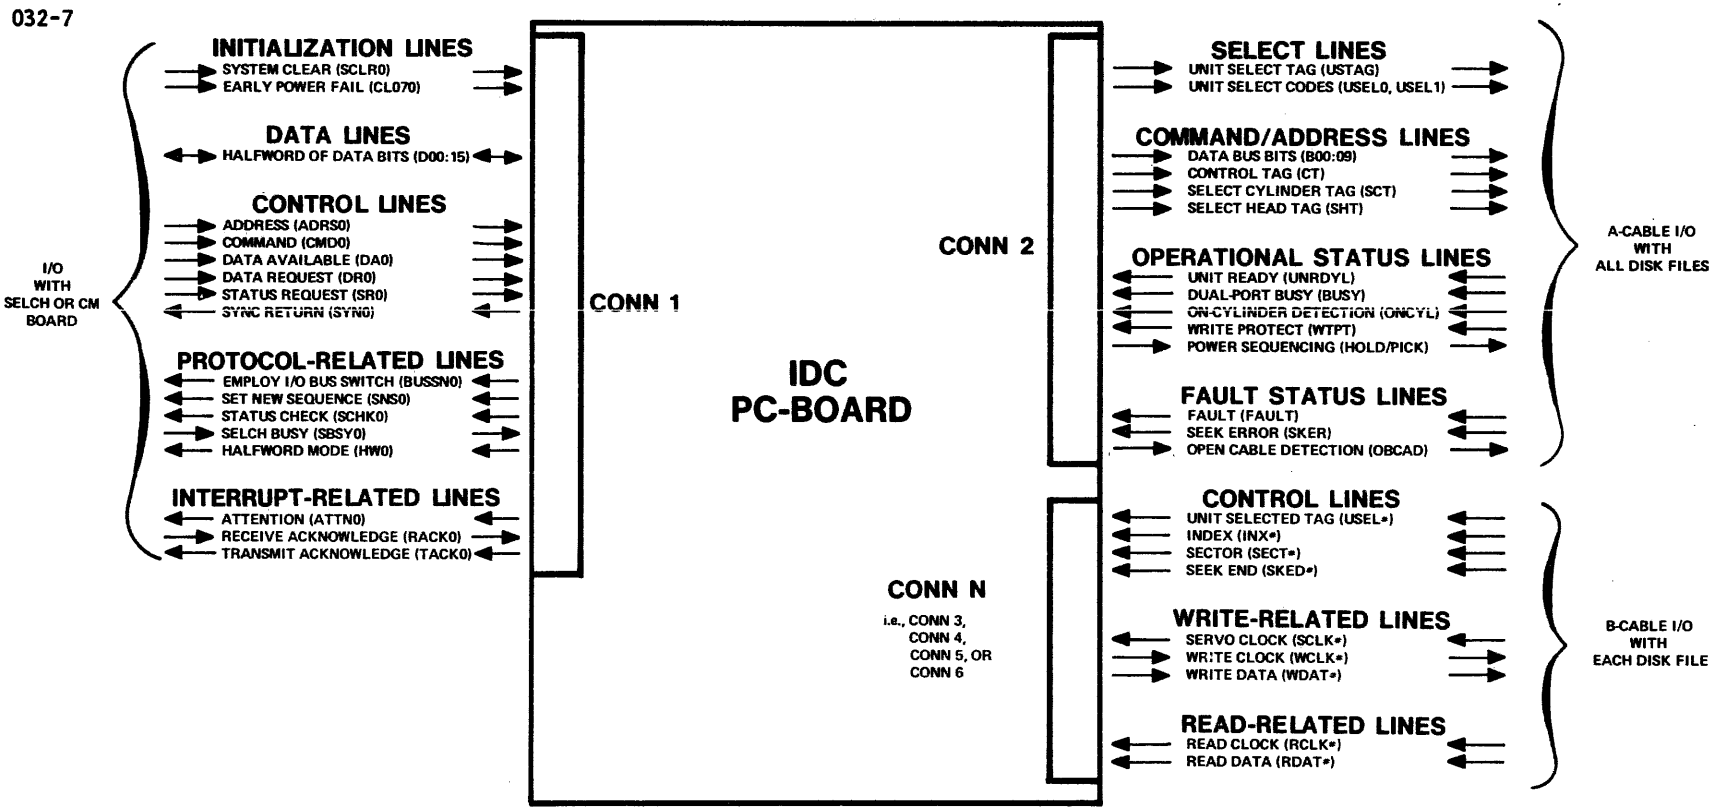

Figure 3-1 Blackbox Diagram of IDC Logic

3.1.1 Input/output (I/O) Lines at Connector 1 (CONN1)

The I/O lines at CONN1 are connected with the SELCH or CM board plugged into the same processor chassis with the IDC or installed under an I/O bus switch (see Figure 3-1). These lines are classified here into five functional groups:

1. Initialization lines
2. Data lines
3. Control lines
4. Protocol-related lines
5. Interrupt-related lines

The following Items, 1 through 5, describe the I/O lines within these groups.

1. Initialization Lines

   This group of lines initializes the IDC logic:

   a. System Clear (SCLR0)

      Input from the processor to initialize IDC logic during a system power up, shutdown or initialization operation.

   b. Early Power Fail (EPF) (CL070)

      Input from the processor to warn the IDC of an imminent power failure.

2. Data Lines

   This group of 16 I/O lines transfers data between the SELCH and the IDC board:

   a. Halfword Data Bits (D00:15)

      SELCH or processor I/O consisting of a halfword or a byte of data. With halfword I/O, data bits D00:15 transfer the data for a read/write operation or the address for a disk cylinder or head. With byte I/O, D08:15 transfer an IDC or disk file address, a processor command, an IDC or disk file status, a sector address or rotational position sensing (RPS) data.

3. Control Lines

This group consists of these I/O lines:

a. Address (ADRS0)

Input from the processor to inform the IDC that data bits D08:15 contain an IDC address or a disk file address. The addressed device is to be selected for subsequent I/O operation.

b. Command (CMD0)

Input from the processor to inform the IDC that data bits D08:15 contain a command for the selected device, i.e.; the IDC or disk file.

c. Data Available (DA0)

Input from the SELCH or processor to inform the IDC that a halfword of data is available on D00:15 for a write operation to IDC.

d. Data Request (DR0)

Input from the SELCH or processor that requests IDC for a halfword of data on D00:15 for a read operation from IDC.

e. Status Request (SR0)

Input from the SELCH or the processor to request an IDC status or disk file status byte from data bits D08:15.

f. Sync Return (SYN0)

IDC output signaling the SELCH or processor that the IDC has properly accepted and responded to a received control line signal.

4. Protocol-Related Lines

This group of lines relates to the protocol exchanges between the SELCH and the IDC board:

a. Employ I/O Bus Switch (BUSSW0)

IDC output informing the SELCH that the IDC employs the new high-speed SELCH protocol with an I/O bus switch.

b. Set New Sequence (SNS0)

IDC output informing the SELCH that the IDC uses new high-speed SELCH protocol without an I/O bus switch.

c. Status Check (SCHK0)

IDC output informing the SELCH of a bad IDC status. This output applies only when the IDC uses the high-speed SELCH protocol.

d. SELCH Busy (SBSY0)

Input from the SELCH to inform IDC that the SELCH is currently busy with a blockdata transfer.

e. Halfword Mode (HW0)

IDC output informing the SELCH that this controller (IDC) is a halfword-oriented device.

5. Interrupt-Related Lines

This group of lines relates to an interrupt request from the IDC board:

a. Attention (ATN0)

IDC output requesting a processor interrupt, placing the IDC into an interrupt pending state.

b. Receive Acknowledge (RACK0)

Input from the processor to acknowledge an interrupt from an IDC; (see Item a). If the IDC has no interrupt pending, it passes the RACK0 signal out as a TACK0 signal to the next IDC board stacked in the processor.

c. Transmit Acknowledge (TACK0)

IDC output consisting of a RACK0 signal received by an IDC having no interrupt pending.

3.1.2 Input/output (I/O) Lines at Connector 2 (CONN2)

The I/O lines at CONN2 are through the A-cable to the attached disk files (see Figure 3-1). These lines are classified here into four functional groups:

1. Select lines

2. Command/address lines

3. Operational status lines

4. Fault status lines

The following Items, numbered 1 through 4, describe the I/O lines within these groups.

1. Select Lines

   This group of lines is involved with the selection of a disk file:

   a. Unit Select Tag (USTAG)

      IDC output informing the attached disk files that the two unit select lines (USEL0 and USEL1, described below) are supplying a binary-coded number, 0-3, to select a disk file.

   b. Unit Select Lines (USEL0, USEL1)

      IDC output consisting of a binary-coded number, 0 through 3, to select a particular disk file for I/O with the IDC.

2. Command/Address Lines

   This group of lines supplies command and address data as control input to a selected disk file:

   a. Data Bus Bits (B00:09)

      IDC output consisting of control or address data, e.g.; a driver command, a cylinder address or a head address. The contents of these lines depends on the three tags discussed in Items b, c and d below.

   b. Control Tag (CT)

      IDC output indicating that B00:09 are supplying a driver command.

   c. Select-Cylinder Tag (SCT)

      IDC output indicating that B00:09 are supplying a cylinder address.

d. Select-Head Tag (SHT)

IDC output indicating that B00:09 are supplying head-select or volume-select data.

3. Operational Status Lines

This group of lines supplies various operational status of a disk file:

a. Unit Ready (UNRDYL)

Disk file output signaling IDC that the selected disk file is ready for I/O with the IDC.

b. Dual-Port Busy (BUSY)

Disk file output applicable only to dual-port operation of a disk file. It informs IDC that the disk file is currently selected by another IDC.

c. On-Cylinder Detection (ONCYL)

Disk file output that signals the IDC once the heads of the selected disk file are positioned over an addressed cylinder.

d. Write Protect (WTPT)

Disk file output informing IDC that the write protect button on the disk file is depressed, i.e.; that the disk file is in the write protect mode.

e. Power Sequencing (HOLD/PICK)

IDC output of a ground signal that picks and holds power sequencing for the attached disk files in the remote mode. (This signal is present when the processor is on and IDC SEQ pins 1 and 2 are not strapped.)

4. Fault Status Lines

This group of lines supplies various fault status of a disk file.

a. Fault (FAULT)

Disk file output informing IDC of a fault condition at a disk file.

b. Seek Error (SKER)

Disk file output informing IDC of a seek error at a disk file.

c. Open Cable Detection (OBCAD)

Disk file output informing IDC of an open cable or a loss of power. This signal prevents IDC from outputting select or control data to the disk file.

3.1.3 Input/Output (I/O) Lines at Connector 3 (CONN3) Through Connector 6 (CONN6)

The I/O lines on any one of these connectors CONN3, CONN4, CONN5 or CONN6 are through a B-cable to a disk file (see Figure 3-1). These lines are classified here into three functional groups:

1. Control lines
2. Write-related lines
3. Read-related lines

The following Items, numbered 1 through 3, describe the I/O lines within these groups.

1. Control Lines

This group of lines passes various control signals to IDC in order to coordinate the transfer of read/write data. The pound (#) symbol with each mnemonic denotes one of four numbers, 0-3, for one of the four possible disk files.

a. Unit Selected Tag (USEL#)

Disk file output signaling IDC that the disk file is now acquired, i.e.; selected, by the IDC.

b. Index (INX#)

Disk file output consisting of a pulse for every disk revolution. This pulse serves as an index for disk sector 0.

c. Sector (SECT#)

Disk file output consisting of a pulse to mark the beginning of each physical sector of an IDC-formatted disk. (See the IDC Programming Manual for a description of a physical sector.)

d. Seek End (SKED#)

Disk file output signaling the end of a seek operation, either successful or unsuccessful.

2. Write-Related Lines

This group of lines relates to write operations from the IDC to a disk file.

a. Servo Clock (SCLK#)

Disk file output used by the IDC as input for the WCLK# signal; see Item b below.

b. Write Clock (WCLK#)

IDC output that synchronizes data written to the disk file.

c. Write Data (WDAT#)

IDC output consisting of data written to the disk file.

3. Read-Related Lines

This group of lines relates to read operations from the disk file to the IDC:

a. Read Clock (RCLK#)

Disk file output that synchronizes data read from the disk file.

b. Read Data (RDAT#)

Disk file output consisting of data read from the disk file.

3.2 INPUT/OUTPUT (I/O) LINES OF THE INTELLIGENT DISK CONTROLLER (IDC) BOARD

This section presents detailed descriptions of the same external I/O lines discussed in Section 3.1. Figure 3-2 shows the connectors of the IDC board and serves as a reference to other figures that illustrate the I/O lines attached to the connector pins. Sections 3.2.1 through 3.2.3 describe these I/O lines.

NOTE

References in these descriptions to the SELCH also apply to the CM.

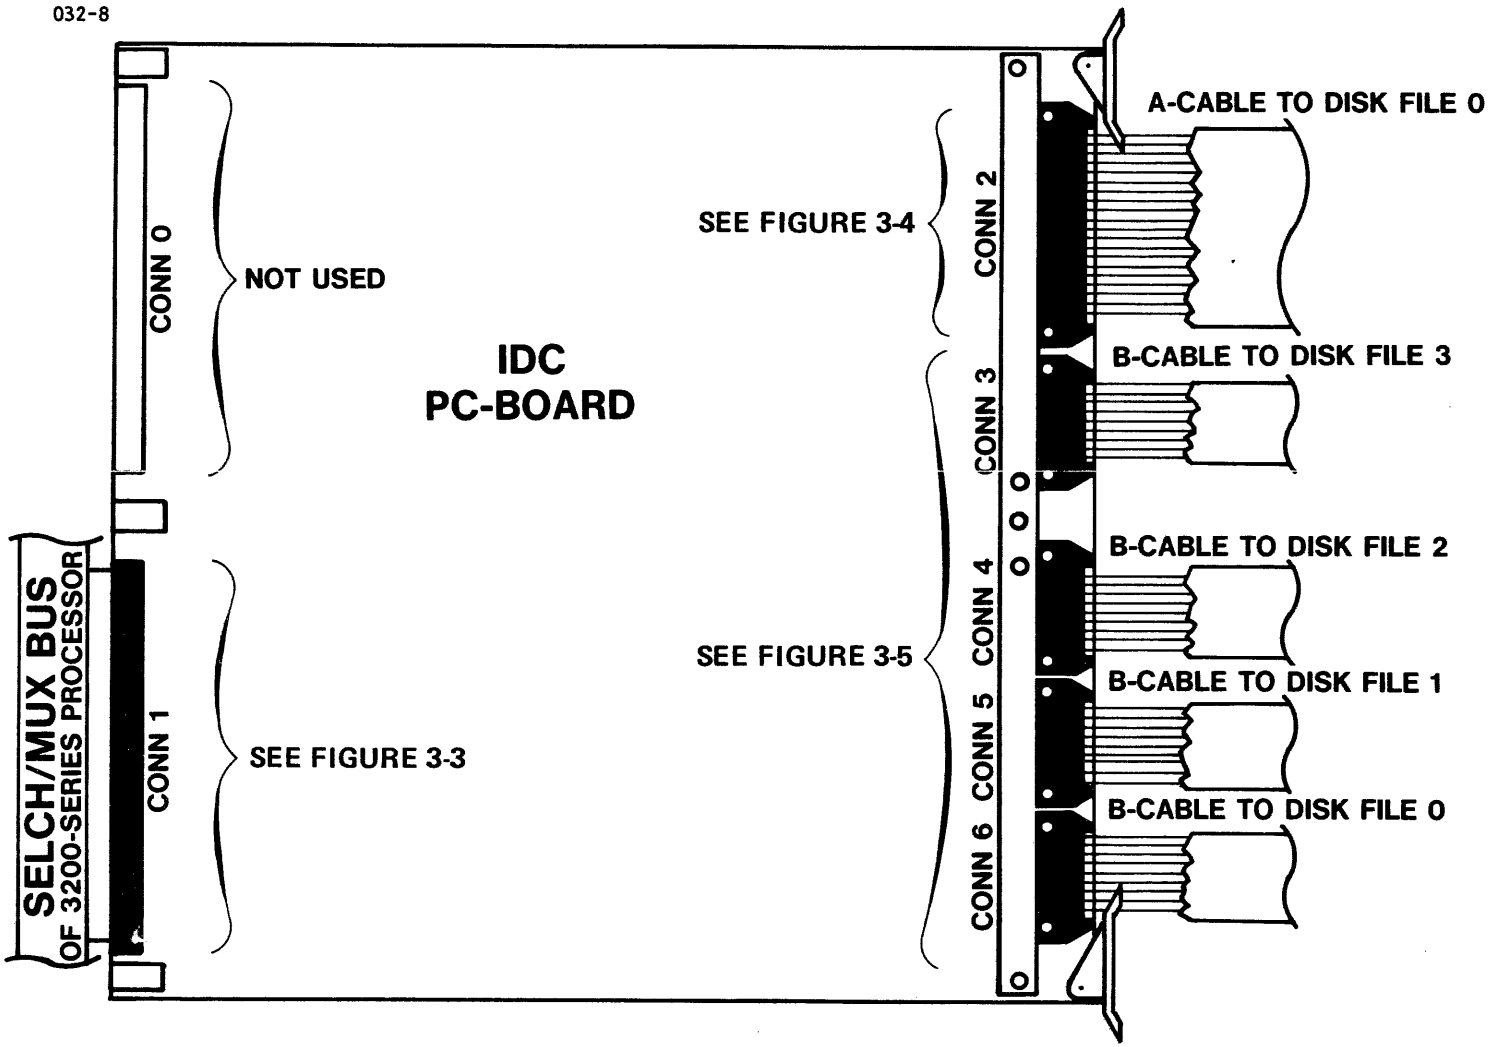

Figure 3-2 Connectors on IDC Board

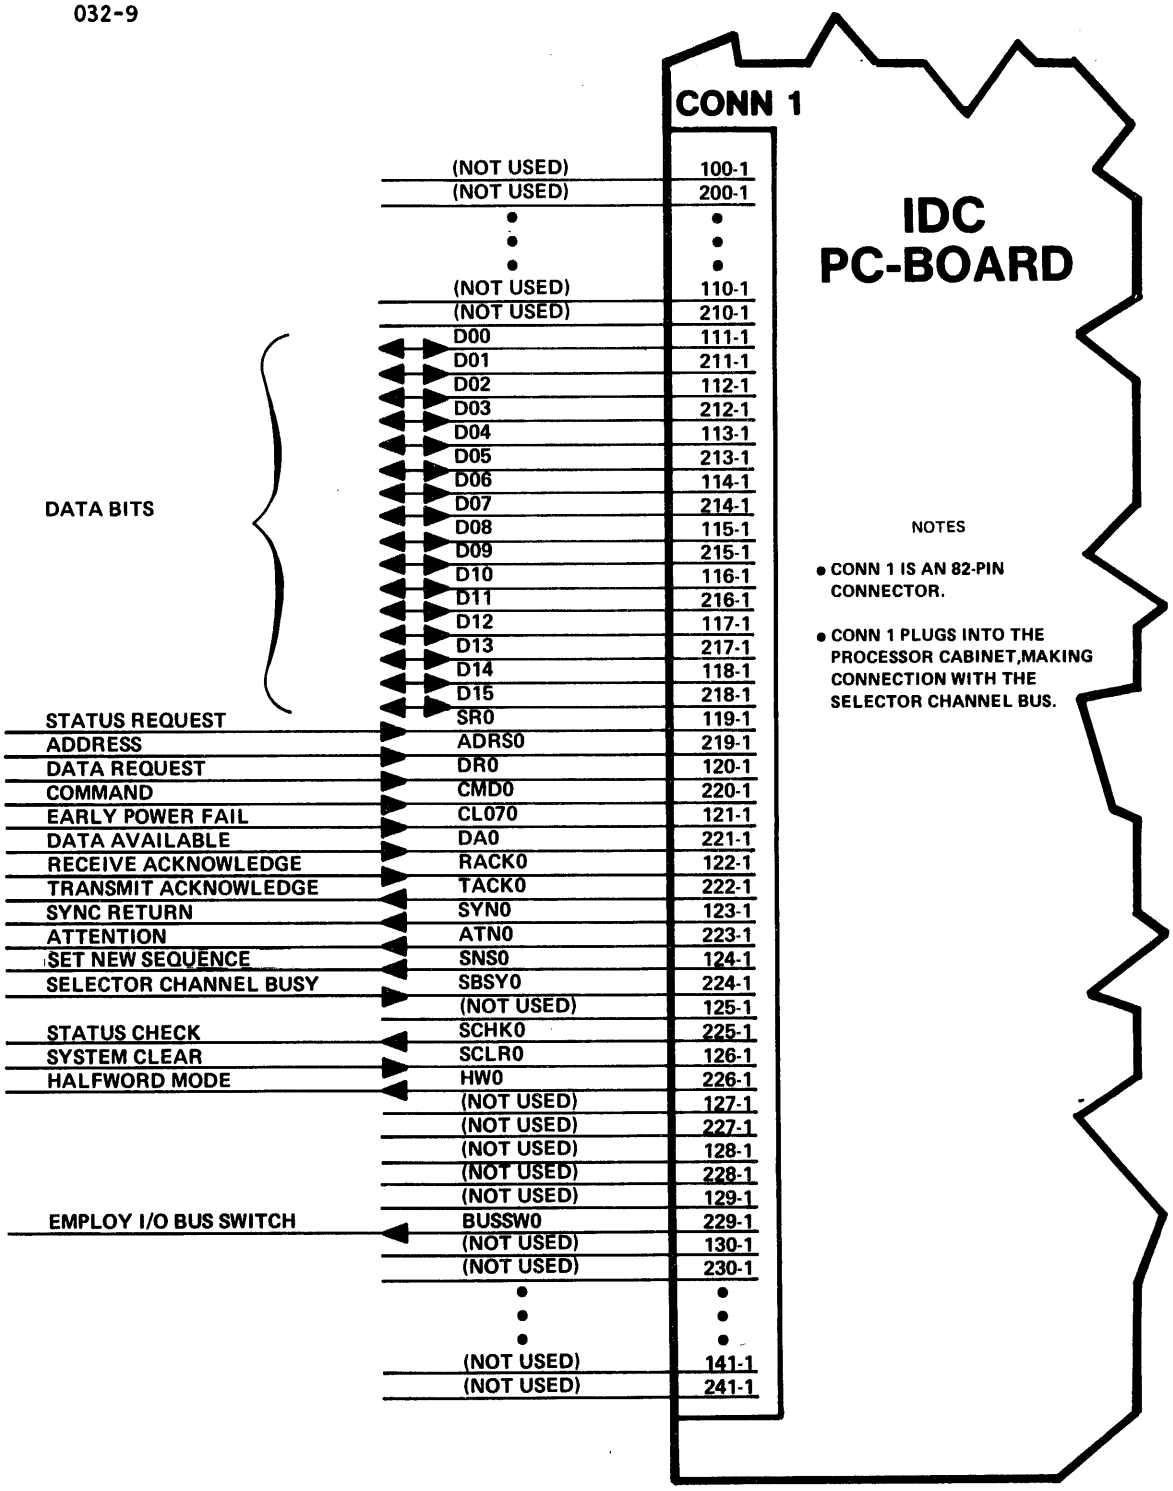

Figure 3-3 IDC CONN1 Connections to SELCH/MUX Bus

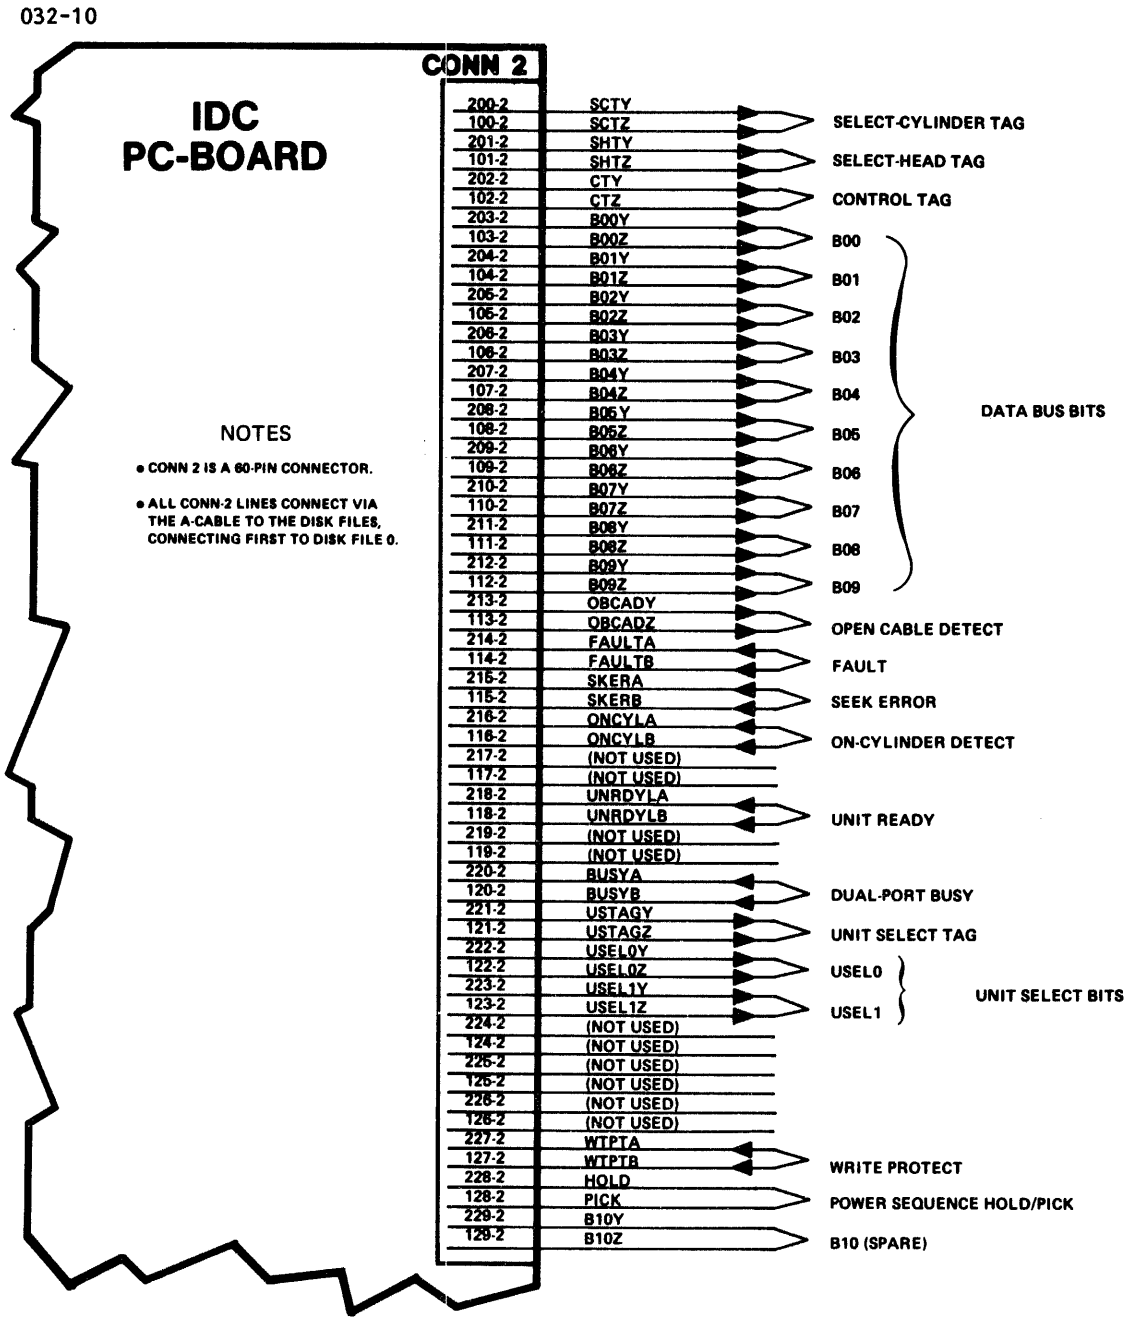

Figure 3-4 IDC CONN2 Connections with A-Cable to Disk Files

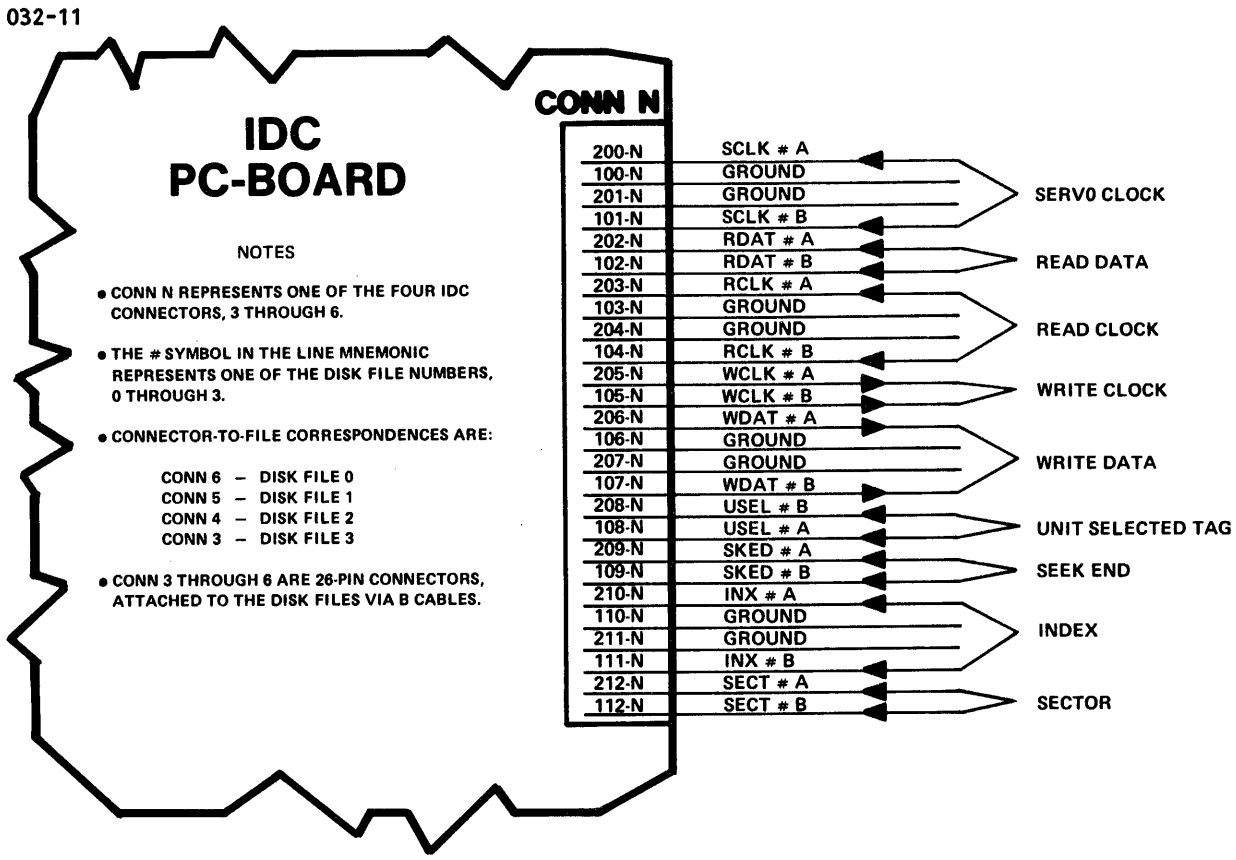

Figure 3-5 IDC CONN3, CONN4, CONN5 and CONN6 Connections with B-Cables to Disk Files

3.2.1 Intelligent Disk Controller (IDC) Connector 1 (CONN1) Pin

Figure 3-3 illustrates and identifies all of the CONN1 pins from the IDC board to the SELCH bus. The following signals, presented alphabetically according to pin mnemonics, describe the inputs and outputs associated with these pins.

a. ADRS0 (Address)

Input from the processor to IDC pin 219-1. When active, this signal informs the IDC that data bits D08 through D15 contain the address of an IDC or a disk file. This address selects a particular device for a subsequent operation, e.g.; a read/write or a status request. ADRS0 must result in device selection before any one of these signals, described below, can have effect: CMD0, DA0, DR0 and SR0.

b. ATN0 (Attention)

Output from IDC pin 223-1 to the processor. When active, this signal indicates that the IDC needs to interrupt the processor. The IDC sends this signal after completing an operation, and consequently has an interrupt pending.

c. BUSSW0 (Employ I/O Bus Switch)

Output from IDC pin 229-1. When active, this signal informs the SELCH that this IDC supports the new high-speed SELCH protocol and employs an I/O bus switch.

NOTE

This signal can be active only if these conditions are met: new-protocol pins W1 and W3 are strapped; toggle 7 of the file 0 address switch is pushed down to the 1 setting; and the IDC is installed under an I/O bus switch.

d. CL070 (EPF)

Input from the processor to IDC pin 121-1. When active, this signal serves as a warning that a power failure is imminent.

e. CMD0 (Command)

Input from the processor to IDC pin 220-1. When active, this signal informs the IDC that data bits D08 through D15 contain a command for the selected IDC or disk file. The IDC Programming Manual discusses these commands.

f. DA0 (Data Available)

Input from the processor or SELCH to IDC pin 221-1. When active, this signal informs the IDC of a write operation to the selected IDC or disk file. Data is available on IDC bits D00 through D15.

g. DR0 (Data Request)

Input from the processor or SELCH to IDC pin 120-1. When active, this signal informs the IDC of a read operation from the selected IDC or disk file to the processor. A halfword of data is read from IDC bits D00 through D15.

h. D00 through D15 (Data Bits 0 through 15)

I/O data on IDC pins 111-1 through 118-1 and 211-1 through 218-1. For halfword I/O, bits D00 through D15 hold read/write data; these bits can also hold a cylinder or head address as input from the processor. For byte I/O, bits D08 through D15 can hold one of the following: processor command, IDC address, IDC status, disk file address, disk file status, sector address and RPS data.

i. HW0 (Halfword Mode)

Output from IDC pin 226-1 to the SELCH. When active, this signal informs the SELCH that this IDC is a halfword-oriented device.

j. RACK0 (Receive Acknowledge)

Input from the processor to IDC pin 122-1. When active, this input indicates an interrupt acknowledgment from the processor. Whenever an IDC sends an ATN0 signal, thereby requesting a processor interrupt, that IDC then has an interrupt pending. The RACK0 input acknowledges this interrupt request. If a RACK0 is received at an IDC having no interrupt pending, that IDC passes this RACK0 as a TACK0 (see its description) to the next IDC in the processor cabinet. That IDC then receives the TACK0 as a RACK0.

In summary, the RACK0 is a daisy-chained interrupt acknowledgment from the processor to an IDC with an interrupt pending.

k. SBSY0 (SELCH Busy)

Input from the SELCH to IDC pin 224-1. When active, this signal indicates that a block data transfer to or from the SELCH is in progress.

l. SCHK0 (Status Check)

Output from IDC pin 225-1 to the SELCH. When active, this signal indicates the occurrence of a bad IDC status: EXAMINE, CONTROLLER IDLE or DATA ERROR. For information on this status, see the IDC Programming Manual. This is applicable only to the high-speed SELCH protocol.

m. SCLR0 (System Clear)

Input from the processor to IDC pin 126-1. When active, this signal causes the initialization of IDC logic. It is active during system power up, shutdown and initialization.

n. SNS0 (Set New Sequence)

Output from IDC pin 124-1 to the SELCH. When active, this signal informs the SELCH that this IDC supports the new high-speed SELCH protocol without an I/O bus switch.

NOTE

This signal can be active only if these conditions are met: the IDC is installed under an I/O bus switch; new protocol pins W1 and W2 are strapped; and toggle 7 of the file 0 address switch is pushed down to the 1 setting. Employing the high-speed protocol by strapping W1 and W2, however, is not a recommended procedure. Standard procedure is to strap W1 and W3 and to employ an I/O bus switch; see Item c above.

o. SR0 (Status Request)

Input signal from the processor or SELCH to IDC pin 119-1. When active, this signal requests the current status of the IDC or an attached disk file. The requested status is passed as one byte of data, bits D08 through D15. The IDC Programming Manual discusses these statuses.

p. SYN0 (Sync Return)

Output from IDC pin 123-1 to the processor or SELCH. When active, this signal informs the processor or SELCH that this IDC has properly accepted and responded to a control line signal.

q. TACK0 (Transmit Acknowledge)

Output from IDC pin 222-1 to the next controller plugged into the I/O slot. This output, consisting of a received RACK0, indicates that this IDC did not have an interrupt pending. See the description above for the RACK0 input.

3.2.2 Intelligent Disk Controller (IDC) Connector 2 (CONN2) Pins

Figure 3-4 illustrates and identifies all of the CONN2 pins and A-cable lines from the IDC board to the disk files. The following items, presented alphabetically according to the line mnemonics, describe the inputs and outputs associated with the A-cable lines.

a. B00Y (differential data bus bit-0 +) and
B00Z (differential data bus bit-0 -)
B09Y (differential data bus bit-9 +) and
B09Z (differential data bus bit-9 -)

Ten output lines, subsequently referred to as B00 through B09, from IDC pins 203-2 and 103-2 (for B00) through pins 212-2 and 112-2 (for B09) to the disk files. These multipurpose bus lines supply control and address data to the attached disk files. The actual content of B00 through B09 depends on one of three tags:

1. CTY/CTZ (differential control tag +/-)

2. SCTY/SCTZ (differential select-cylinder tag +/-)

3. SHTY/SHTZ (differential select-head tag +/-)

As shown in Table 3-1, B00 through B09 can supply a control function, a cylinder address or a head address depending on which of the three tags is active. For further information on bus line contents, see the subsequent tag descriptions.

TABLE 3-1 BUS LINE CONTENTS CORRESPONDING TO ACTIVE OUTPUT TAG

BUS LINE	CONTROL* FUNCTION	CYLINDER** ADDRESS	HEAD*** ADDRESS
B00	Write Gate	1	1
B01	Read Gate	2	2
B02	Servo Offset +	4	4
B03	Servo Offset -	8	8
B04	Fault Clear	16	16
B05	(Not Applicable)	32	N/A
B06	Return to Zero (RTZ)	64	N/A
B07	Data Strobe Early	128	N/A
B08	Data Strobe Late	256	N/A
B09	Release (Dual-Port Operation)	512	N/A

* Applies when CTY/CTZ tag is active.
** Applies when SCTY/SCTZ tag is active.
*** Applies when SHTY/SHTZ tag is active.

b. B10Y (differential data bus bit-10 +) and
B10Z (differential data bus bit-10 -)

This is a spare differential data bus line.

c. BUSYA (differential dual-port busy +) and
BUSYB (differential dual-port busy -)

Input from a disk file to IDC pins 220-2 and 120-2, applicable only to dual-port operation of a particular disk file. When active, this line indicates to the IDC that the selected disk file has been acquired by another IDC.

d. CTY (differential control tag +) and
CTZ (differential control tag -)

Output from IDC pins 202-1 and 102-2 to the disk files. When active, this input tag informs the disk files that bus lines B00 through B09 are supplying a binary-coded control function (i.e.; a disk driver command). Table 3-2 lists and describes the control functions corresponding to the settings of these ten bus lines.

TABLE 3-2 CONTROL FUNCTIONS ACTIVATED BY CONTROL TAG CTY/CTZ

BUS* LINE	CONTROL FUNCTION	DESCRIPTION
B00	Write Gate	Informs the selected disk drive (selected by USEL0 and USEL1 on the A-cable) that the IDC will write data over the write data line of the B-cable to the current location of the disk medium.
B01	Read Gate	Informs the selected disk drive that the IDC will read data over the read data line of the B-cable from the current location of the disk medium.
B02	Servo Offset +	Offsets the head of the selected disk file in a positive direction, i.e.; towards the spindle of the disk drive.
B03	Servo Offset -	Offsets the head of the selected disk file in a negative direction, i.e.; away from spindle.
B04	Fault Clear	Clears the fault condition that resulted from a DC power failure, a simultaneously active read gate and write gate, or a selection of a nonexistent head. (See the description for the FAULTA/FAULTB line.)
B05	------	Not applicable. Must equal zero.
B06	Return to Zero	Restores the selected disk file to cylinder 000.
B07	Data Strobe Early	Causes the disk file to advance the read clock in order to retrieve marginal data.
B08	Data Strobe Late	Causes the disk file to retard the read clock in order to retrieve marginal data.
B09	Release	Releases a dual-port operational disk file so another processor can access it.

* These ten lines are read as a binary number with B00 representing 2 to the 0 power, B01 representing 2 to the first power, B02 representing 2 to the second power, and so forth.

e. FAULTA (differential fault +) and
FAULTB (differential fault -)

Input from a disk file to IDC pins 214-2 and 114-2. When active, this line indicates a fault condition at a disk file.

f. HOLD/PICK (power sequence hold/pick)

A power sequencing ground provided by IDC logic from pins 228-2 and 128-2 to attached disk files. If SEQ pins 1 and 2 are not strapped and if attached disk files have their local/remote switch in the remote position, the IDC logic switches a ground onto these lines to permit power sequencing once the processor is turned on. When the processor is turned off, IDC logic removes the ground to power-down disk files. Essentially, these lines pick and hold the power sequencing capability.

g. OBCADY (differential open cable detection +) and
OBCADZ (differential open cable detection -)

Output from IDC pins 213-2 and 113-2 to a disk file. When active, this line indicates an open A-cable or a loss of IDC power. While this condition exists, no selection or control data will be sent from the IDC.

h. ONCYLA (differential on-cylinder detection +) and
ONCYLB (differential on-cylinder detection -)

Input status from a disk file to IDC pins 216-2 and 116-2. When active, this line signals the IDC that the heads of the selected disk file are positioned, i.e.; in response to a Seek instruction, they are positioned over a selected track. The on-cylinder status clears with another Seek instruction, and again becomes active once the heads are positioned. A carriage offset results in the loss of the on-cylinder status for 2.75ms (nominal), i.e.; about 2.75ms are required to move the head to a +/- offset.

i. SCTY (differential select-cylinder tag +) and
SCTZ (differential select-cylinder tag -)

Output from IDC pins 200-2 and 100-2 to the disk files. When active, this output tag informs the disk file that the ten bus lines, B00 through B09, are supplying a binary-coded cylinder address. B00 represents 2 to the 0 power, B01 represents 2 to the first power, etc.

j. SHTY (differential select-head tag) and
SHTZ (differential select-head tag)

Output from IDC pins 201-2 and 101-2 to the disk files. When active, this output tag informs the disk file that B00 through B09 are supplying head-select or volume-select data.

For a mass storage media (MSM) file, bus lines B00 through B04 supply head-select data, where B00 represents 2 to the 0 power, B01 represents 2 to the first power, etc. See Table 3-1 for further illustration.

For a medium capacity cartridge disk drive (MCCDD) bit-B04 represents a volume select bit; B00 through B03 are nonapplicable. B04, which represents 2 to the fourth power, supplies part of the data for a volume-select address: when reset, it denotes a removable disk; when set, it denotes a fixed disk. The remainder of the volume-select address is supplied by another input, a cylinder address, on B00 through B09. This input is associated with the select-cylinder tag SCTY/SCTZ. In summary, supplying a volume-select address to an MCCDD requires two tag sequences:

1. An active SHTY/SHTZ tag with bus line B04 set or reset.

2. An active SCTY/SCTZ tag with bus lines B00 through B09 containing a valid cylinder address. (The worst-case switching delay is 4ms.)

k. SKERA (differential seek error +) and
SKERB (differential seek error -)

Input from a disk file to IDC pins 215-2 and 115-2. When active, this line indicates that a seek error occured at a disk file. A seek error refers to one of these three conditions:

1. The disk drive could not move the head within a specified time interval.

2. The disk drive moved the head to a position outside the recording area of the disk.

3. The disk drive received an illegal track address.

A seek error can be cleared only by an RTZ control function.

l. UNRDYLA (differential unit ready +) and
UNDRYLB (differential unit ready -)

Input from a disk file to IDC pins 218-2 and 118-2. When active, this line indicates that the selected disk file is up-to-speed, that the heads are positioned over the recording tracks, and that no fault condition exists within the disk file.

m. USEL0Y (differential unit select 0 +),
USEL0Z (differential unit select 0 -),
USEL1Y (differential unit select 1 +), and
USEL1Z (differential unit select 1 -)

Two output lines, subsequently referred to as USEL0 and USEL1, from IDC pins 222-2 and 122-2 (for USEL0) and pins 223-2 and 123-2 (for USEL1). These binary-coded lines supply a number, 0 through 3, of the disk file to be selected. USEL0 represents 2 to the 0 power; USEL1 represents 2 to the first power.

n. USTAGY (differential unit select tag +) and
USTAGZ (differential unit select tag -)

Output from IDC pins 221-2 and 121-2 to the disk files. When active, this output tag informs the disk files that the two unit-select lines, USEL0 and USEL1, are supplying a binary-coded number, as mentioned above.

o. WTPTA (differential write protect +) and
WTPTB (differential write protect -)

Input from a disk file to IDC pins 227-2 and 127-2. When active, this line indicates that the particular disk file is in write-protected mode: a write-protect button on the disk file has been depressed.

3.2.3. Intelligent Disk Controller (IDC) Connector 3 (CONN3) Through Connector 6 (CONN6) Pins

Figure 3-5 illustrates and identifies all of the pins and B-cable lines from these IDC connectors: CONN3, CONN4, CONN5 and CONN6. The following Items, presented alphabetically according to line mnemonics, describe the inputs and output associated with the lines. These descriptions, which apply to all four connectors, use the letter N to represent the connector numbers (3, 4, 5 or 6) and the pound (#) symbol to represent the disk file number (0, 1, 2 or 3).

a. INX#A (differential index +) and
INX#B (differential index -)

Input from disk file # to IDC pins 210-N and 111-N. This line receives a pulse for every disk revolution. The leading edge of the pulse is treated as the leading edge of sector 0. Pulse width is typically 2.5ms.

b. RCLK#A (differential read clock +) and
RCLK#B (differential read block -)

Input from disk file # to IDC pins 203-N and 104-N. The IDC uses this input to clock-in, or synchronize, data read from disk file #.

c. RDAT#A (differential read data +) and
RDAT#B (differential read data -)

Input from disk file # to IDC pins 202-N and 102-N. This line carries read data from disk file #. Read data is in NonReturn to zero (NRZ) form.

d. SCLK#A (differential servo clock +) and
SCLK#B (differential servo clock -)

Input from disk file # to controller pins 200-N and 101-N. The IDC uses this input as the write clock; see WCLK#A/WCLK#B below.

e. SECT#A (differential sector +) and
SECT#B (differential sector -)

Input from disk file # to IDC pins 212-N and 112-N. This input pulse marks the beginning of each physical sector of the IDC-formatted disk. (There are 33 physical sectors per disk revolution.)

f. SKED#A (differential seek end +) and
SKED#B (differential seek end -)

Input from disk file # to IDC pins 209-N and 109-N. This input line is a combination of the on-cylinder detect line (ONCYLA/ONCYLB) and the seek error line (SKERA/SKERB). These two lines connect through the A-cable to IDC CONN2. It indicates to the IDC that a seek operation has ended, either successfully or unsuccessfully.

g. USEL#A (differential unit selected tag +) and
USEL#B (differential unit selected tag -)

Input from disk file # to IDC pins 108-N and 208-N. It indicates that the attached disk file is now acquired by the IDC, i.e.; the disk has been selected.

h. WCLK#A (differential write clock +) and
WCLK#B (differential write clock -)

Output from IDC pins 205-N and 105-N to disk file #. The IDC uses this output to clock-out, or synchronize, data written to the disk file.

i. WDAT#A (differential write data +) and
WDAT#B (differential write data -)

Output from IDC pins 206-N and 107-N to disk file #. This line carries write data to be recorded on the disk. Written data is in NRZ form.

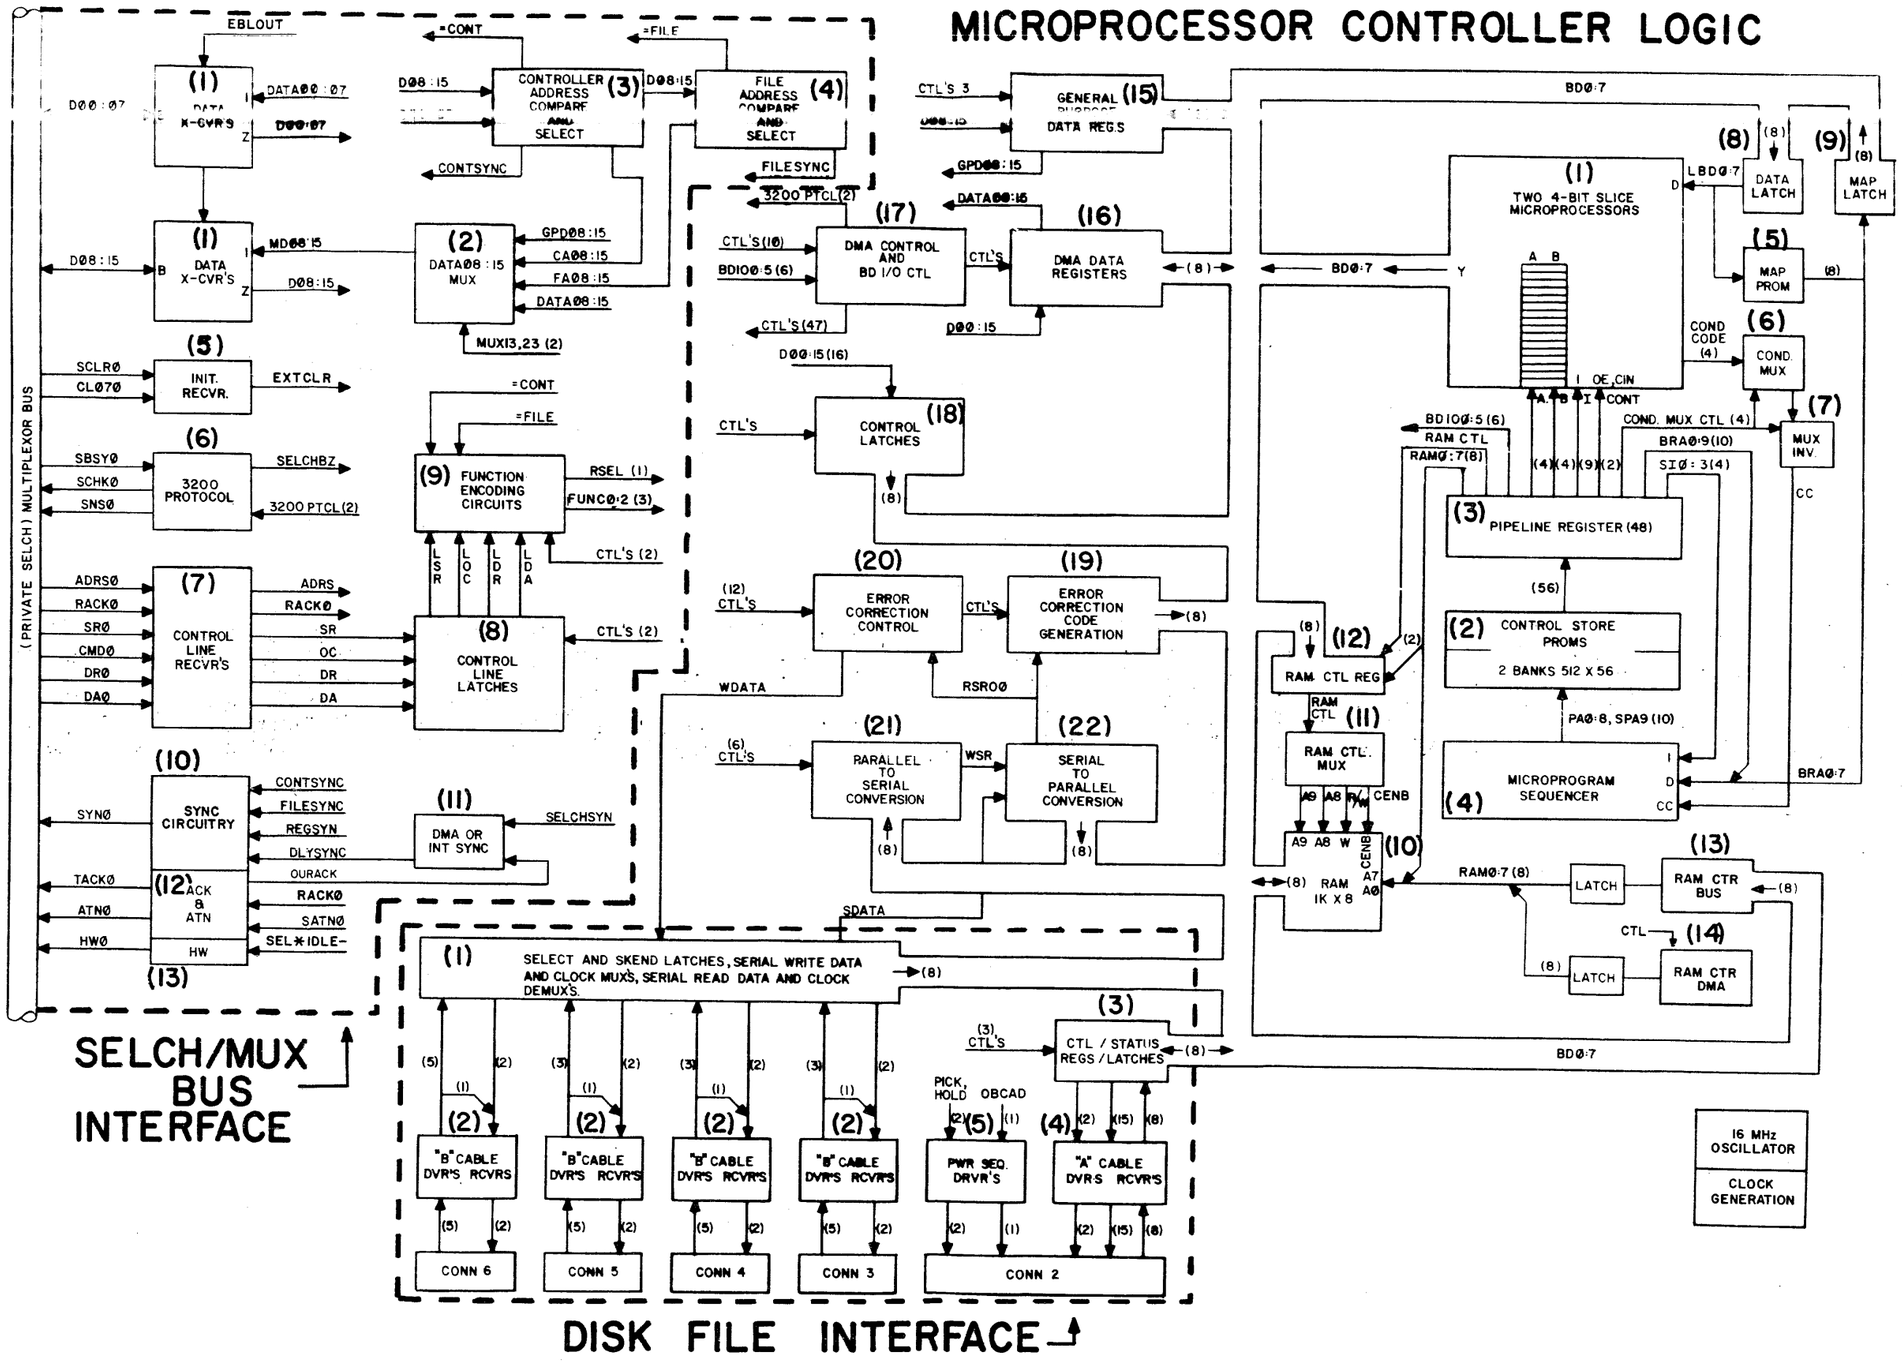

Figure 3-6 Block Diagram of the IDC Logic

3.3 BLOCK DIAGRAM ANALYSIS OF INTELLIGENT DISK CONTROLLER (IDC)

Figure 3-6 is a block diagram of the IDC logic circuitry. As shown, this block diagram has three logical sections:

1. SELCH/MUX bus interface

2. Disk file interface

3. Microprocessor controller logic

Section 3.3.1 describes the constituent blocks for the SELCH/MUX bus interface; Section 3.3.2, the disk file interface; and Section 3.3.3, the microprocessor controller logic.

3.3.1 SELCH/MUX Bus Interface

This portion of the IDC board serves as the interface to the SELCH/MUX bus. It consists of thirteen functional blocks:

1. Data Transceivers
2. Data Multiplexer for Bits 08:15
3. Controller Address Compare-and-Select Circuitry
4. File Address Compare-and-Select Circuitry
5. Initialization Receiver
6. 3200-Protocol Circuitry
7. Control Line Receivers
8. Control Line Latches
9. Function Encoding Circuits
10. Synchronization Circuitry
11. DMA and Interrupt Sync Circuits
12. Acknowledgment and Attention Circuitry
13. Halfword-Mode Circuitry

The following Items describe these functional blocks and their associated I/O lines.

1. Data Transceivers

   Transmit data to or receive data from the SELCH/MUX bus. I/O lines are:

   a. EBLOUT (driver control), input

      Signal for setting the transceiver mode to transmit or receive.

   b. D00:15 (data bits D00 through D15), I/O

      Data to or from the SELCH/MUX bus. See Section 3.2.1 for a more complete description.

c. DATA00:07 (data bits 00 through 07), input

More significant byte of Direct Memory Access (DMA) data to be transmitted to the SELCH.

d. MD08:15 (multiplexed data bits 08 through 15), input

One of four multiplexed data sources to be sent to the SELCH or processor.

e. D00:07 (receive data bits 00 through 07), output

More significant byte of data received from the SELCH/MUX bus, i.e.; from the processor or SELCH.

f. D08:15 (receive data bits 08 through 15), output

Less significant byte of data received from the SELCH/MUX bus, i.e.; from the processor or SELCH.

2. Data Multiplexer for Bits 08:15

Selects one of four data sources as MD08:15 input to the data transceivers. I/O lines are:

a. MUX13,23 (multiplexer control bits), input

Binary value for selecting one of the following four data-source inputs.

b. GPD08:15 (general-purpose data), input

General purpose control data like status, RPS, etc.; to be sent as MD08:15 input to the data transceivers.

c. CA08:15 (controller-address bits 08 through 15), input

IDC address (of this controller) to be sent as MD08:15 input to the data transceivers.

d. FA08:15 (file-address bits 08 through 15), input

File address (of a disk file attached to this controller) to be sent as MD08:15 input to the data transceivers.

e. DATA08:15 (data bits 08 through 15), input

Less significant byte of DMA data to be transmitted, via the data transceivers, to the SELCH.

f. MD08:15 (multiplexed data bits 08 through 15), output

One of four multiplexed data sources to be sent to the SELCH or processor.

3. Controller Address Compare-and-Select Circuitry

Detects when this IDC is addressed by the processor. More specifically, this circuitry compares a received controller address with the address of this IDC; if the two addresses match, then this IDC is selected for I/O with the processor via the SELCH/MUX bus. (The IDC address is determined by the setting of the controller address switch on the IDC board, discussed in Section 2.4.1.) I/O lines are:

a. D08:15 (receive data bits 08 through 15), input

   Controller address received from the processor.

b. D06:07 (receive data bits 06 and 07), input

   Controller address bits appended to D08:15 for a full 10-bit address selection. These two bits must equal zero for address comparison to occur.

c. =CONT (equals controller), output

   Signal for indicating that the received controller address matches the address of this IDC.

d. CONTSYNC (controller sync return), output

   A sync signal indicating that the IDC has properly accepted and responded to control line signals.

e. CA08:15 (controller-address bits 08 through 15), output

   IDC address (of this controller) to be sent to the processor, along with the sync signal SYN0.

4. File Address Compare-and-Select Circuitry

Detects when an attached disk file is addressed by the processor. More specifically, this circuitry compares a received disk file address with the addresses of the disk files attached to this IDC; if there is a match, then the addressed disk file is selected for I/O with the processor via the SELCH/MUX bus. (Disk file addresses are determined by the setting of the file 0 address switch on the IDC board, discussed in Section 2.4.1.) I/O lines are:

a. D08:15 (receive data bits 08 through 15), input

   Disk file address received from the processor.

b. =FILE (equals file), output

Signal for indicating that the received file address matches the address of a disk file at this IDC.

c. FILESYNC (file sync return), output

A sync signal indicating that an attached disk file has properly accepted and responded to control line signals.

d. FA08:15 (file address bits 08 through 15), output

File address (of the selected disk file) to be sent to the processor, along with the sync signal SYN0.

5. Initialization Receiver

Initializes IDC logic to permit controller comunication with the Series-3200 Processor, or to prepare the IDC logic for an imminent power failure. I/O lines are:

a. SCLR0 (system clear), input

Signal from the processor for initializing IDC circuitry. See Section 3.2.1 for more information.

b. CL070 (early power fail), input

Signal from the processor as a warning that a power failure is about to occur. See Section 3.2.1.

c. EXTCLR (external clear), output

Signal for initializing the IDC logic.

6. 3200-Protocol Circuitry

Enables the IDC to employ the new high-speed SELCH protocol. This protocol applies only when the New Protocol pins W1 and W3 or W1 and W2 are strapped. I/O lines are:

a. SBSY0 (SELCH busy), input

Signal for indicating that the SELCH is currently busy with a block-data transfer. See Section 3.2.1 for further description.

b. SELCHBZ (SELCH busy), output

Same description as above with SBSY0.

c. 3200 PTCL (3200 protocol), input

Data indicating the occurrence of a bad IDC status, namely: S13, EXAMINE; S14, CONTROLLER IDLE; or S15, DATA ERROR. The indicated status results from bits 13, 14 and 15 of a status register within the Random Access Memory (RAM) circuitry. See the IDC Programming Manual for further description. (Physically, 3200 PTCL represents two lines: STCHK and CTLOPTC. See Appendix A for further description.)

d. SCHK0 (status check), output

Output to SELCH to indicate a bad IDC status associated with the high-speed SELCH protocol. See Item c above. See Section 3.2.1 for more information.

e. SNS0 (set new sequence), output

Signal for indicating that the controller is set-up for the optional new high-speed SELCH protocol. This signal results when toggle 7 of the file 0 address switch is pushed down to the 1 setting, and when the New Protocol pins W1 and W2 are strapped. See Sections 2.4.1 and 2.4.2 for detailed information.

7. Control Line Receivers

Receive control signals from the SELCH/MUX bus. I/O lines are:

a. ADRS0 (address), input

Signal indicating that D08:15 (input lines to the data transceivers) contain the address of an IDC or disk file. This signal must result in device selection at the IDC before any one of these signals, described below, can have effect: SR0, CMD0, DR0 and DA0. See Section 3.2.1 for more information.

b. ADRS (address), output

Same description as above with ADRS0.

c. RACK0 (receive acknowledgment), input

Signal acknowledging that the processor received an ATN0 from an IDC with an interrupt pending, possibly this one. In effect, RACK0 acknowledges an interrupt request signaled by the ATN0 signal. See Section 3.2.1 for a more complete description.

d. RACK0 (receive acknowledgment), output

Same description as above. If the IDC does not have an interrupt pending, RACK0 is passed as TACK0 output to the next IDC in the I/O slot of the processor cabinet. See Item 12 below for further description.

e. SR0 (status request), input

Signal for requesting the status of a selected IDC or disk file. See Section 3.2.1 for further description.

f. SR (status request), output

Same description as above with SR0.

g. CMD0 (command), input

Signal indicating that input lines D08:15 contain a command for this selected IDC or for a selected disk file. See Section 3.2.1 for further description.

h. OC (output command), output

Same description as above with CMD0.

i. DR0 (data request), input

Signal indicating a read operation from output lines D00:15. See Section 3.2.1 for further description.

j. DR (data request), output

Same description as above with DR0.

k. DA0 (data available), input

Signal indicating a write operation from the processor to input lines D00:15. See Section 3.2.1 for further description.

l. DA (data available), output

Same description as above with DA0.

8. Control Line Latches

Temporarily store (i.e.; latch) control inputs for later use by the IDC microprocessor logic. I/O lines are:

a. CTL'S (control lines), input

Binary coded control lines to enable or disable latching of the four control inputs SR, OC, DR and DA.

b. SR (status request), input

Control input resulting from a received SR0 signal.

c. LSR (latched status request), output

Latch signal corresponding to the above SR input.

d. OC (output command), input

Control input resulting from a received CMD0 signal.

e. LOC (latched output command), output

Latch signal corresponding to the above OC input.

f. DR (data request), input

Control input resulting from a received DR0 signal.

g. LDR (latched data request), output

Latch signal corresponding to the above DR input.

h. DA (data available), input

Control input resulting from a received DA0 signal.

i. LDA (latched data available), output

Latch signal corresponding to the above DA input.

9. Function Encoding Circuits

Encodes the latched control lines (LSR, LOC, LDR and LDA) into a 3-bit code for a selected IDC or disk file. I/O lines are:

a. LSR (latched status request), input

Latch signal corresponding to the SR0 input from the SELCH/MUX bus.

b. LOC (latched output command), input

Latch signal corresponding to the CMD0 input from the SELCH/MUX bus.

c. LDR (latched data request), input

Latch signal corresponding to the DR0 input from the SELCH/MUX bus.

d. LDA (latched data available), input

Latch signal corresponding to the DA0 input from the SELCH/MUX bus.

e. FUNC0:2 (function code), output

Binary coded signal representing one of eight possible functions. This output goes onto the microprocessor bus, BD0:7, when RSEL is also active. See Appendix A for further description.

f. RSEL (register select), output

Signal indicating that the encoded FUNC0:2 bits are now active.

g. CTL'S (control lines), input

Control lines to gate the FUNC0:2 bits onto BD0:7.

h. =CONT (equals controller), input

Signal for indicating that the FUNC0:2 bits apply to this selected IDC.

i. =FILE (equals file), input

Signal for indicating that the FUNC0:2 bits apply to a selected disk file.

10. Synchronization Circuitry

Receives synchronization signals from the IDC logic and ouputs a synchronization signal to the processor or SELCH. I/O lines are:

a. CONTSYNC (controller sync return), input

Sync signal indicating that this IDC has properly accepted and responded to a control line signal.

b. FILESYNC (file sync return), input

Sync signal indicating that a selected disk file attached to this IDC has properly accepted and responded to a control line signal.

c. REGSYN (register sync), input

Sync signal indicating that the IDC received one of the four control functions SR0, CMD0, DR0 or DA0. See Item 7 above for more information.

d. DLYSYNC (delayed sync return), input

Either the DMA sync signal to the SELCH (resulting from SELCHSYN) or the interrupt-acknowledgment sync signal (resulting from OURACK0) to the processor. See Item 11 below for further description.

e. SYN0 (sync return), output

Sync signal informing the processor or SELCH that this IDC or an attached disk file has properly accepted and responded to control line signals. See the corresponding description in Section 3.2.1.

11. DMA and Interrupt Sync Circuits

Outputs a delayed sync signal resulting from either SELCHSYN or OURACK0. I/O lines are:

a. SELCHSYN (SELCH sync return), input

Sync return in response to a DMA transfer with the SELCH. (Physically, SELCHSYN represents two lines: DMASR and XFRSYNCH. See Appendix A for further description.)

b. OURACK0 (our RACK0), input

Signal indicating that a RACK0 signal was received by this IDC, which had an interrupt pending.

c. DLYSYNC (delayed sync return), output

A DMA sync signal (resulting from SELCHSYN) to the SELCH or an interrupt-acknowledgment sync signal (resulting from OURACK0) to the processor.

12. Acknowledgment and Attention Circuitry

Handles controller interrupt requests (ATN0) and interrupt acknowledgments (RACK0/TACK0). I/O lines are:

a. RACK0 (receive acknowledge), input

Signal (resulting from a received RACK0) acknowledging that the processor received an interrupt request (ATN0 signal) from a controller.

b. OURACK0 (our RACK0), output

Signal indicating that the received RACK0 signal was for this IDC, which had an interrupt pending. If this IDC had no interrupt pending, output would be TACK0 instead of OURACK0.

c. TACK0 (transmit acknowledge), output

Signal, consisting of a received RACK0, passed onto the next controller in the processor cabinet. See Section 3.2.1 for further description.

d. SATN0 (set attention), input

Signal for activating ATN0 output.

e. ATN0 (attention), output

Signal indicating that this IDC wants to interrupt the processor, i.e.; that this IDC has an interrupt pending. See Section 3.2.1 for further description.

13. Halfword-Mode Circuitry

Informs the SELCH that this controller is in the halfword-mode of operation via lines D00 through D15. I/O lines are:

a. SEL*IDLE- (selected and not idle), input

Signal indicating that this IDC is selected and is not idle. It activates the HW0 output. (Physically, SEL*IDLE- represents two lines: CONTSEL and IDLE. See Appendix A for further description.)

b. HW0 (halfword-mode), output

Signal informing the SELCH that this IDC is a halfword-oriented device. See Section 3.2.1 for more information.

3.3.2 Disk File Interface

This portion of the IDC board serves as the interface to the disk files. It consists of five functional blocks:

1. Select and Seek-End (SKEND) Latches, serial-write-data and clock multiplexers (MUXs), and serial-read-data and clock demultiplexers (DEMUXs)

2. B-cable drivers/receivers

3. Control and status registers/latches

4. A-cable drivers/receivers

5. Power sequencing drivers

The following Items describe these functional blocks and their associated I/O lines.

1. Select and Seek-End (SKEND) Latches, Serial-write-data and clock multiplexers (MUXs), and Serial-read-data and clock demultiplexers (DEMUXs)

   These circuits serve as the interface between the 8-bit microprocessor bus, BD0:7, and the B-cable circuitry to the disk drives. Select latches are available for selecting one of four possible disk drives attached to the IDC; SKEND latches are available for signaling a seek end from the drives. MUXs transmit serial write data and clock signals to the disk drives. And in the other direction, DEMUXs receive serial read data and clock signals from the disk drives. Associated with these MUX and DEMUX operations are write clocks, write data registers, and read clocks. I/O lines are:

   a. WDATA (serial write data), input

      Serial data, along with error correction code (ECC), to be written to a disk file.

   b. SDATA (serial read data), output

      Serial data, along with ECC, read from a disk file.

   c. BD0:7 (bus data lines 0 through 7), I/O

      Various data and control bytes.

      NOTE

      BD0:7 is the 8-bit microprocessor bus of the IDC -- the main data path among the the functional blocks, or modules, of the IDC.

   d. Driver Lines (not labeled), Output

      Serial write data and clock signals to the B-cable drivers.

e. Receiver Lines (not labeled), Input

Serial read data and clock signals from the B-cable receivers.

2. B-Cable Drivers/Receivers

B-cable drivers receive serial write data and clock signals from the MUXs and transfer them to the disk files. B-cable receivers receive serial data and clock signals from the disk files and transfer them to the DEMUXs. For detailed descriptions of all I/O lines connected to the drivers/receivers via these four connectors, CONN3 through CONN6, see Sections 3.1.3 and 3.2.3.

3. Control and Status Registers/Latches

Latch data and controls associated with the A-cable. I/O lines are:

a. BD0:7 (bus data lines 0 through 7), I/O

Various data and controls to and from the registers and latches.

b. CTL'S (control lines), input

Control signals to latch or enable data and controls for BD0:7.

c. Driver/Receiver Lines (not labeled), I/O

See Item 4 below.

4. A-Cable Drivers/Receivers

By means of registers and latches, A-cable drivers receive various data and controls from BD0:7 and transfer them to the disk files. A-cable receivers receive data and controls from the disk files and transfer them to BD0:7 by means of registers and latches. For detailed descriptions of all I/O lines connected to the A-cable drivers/receivers via CONN2, see Sections 3.1.2 and 3.2.2.

5. Power Sequencing Drivers

Control the power sequencing grounds, PICK and HOLD, and the open cable detect signal. I/O lines are:

a. PICK,HOLD (power sequence pick/hold), I/O

Signals for enabling or disabling power sequencing. Both of these signals are active (ground) when IDC SEQ pins 1 and 2 are not strapped and when the processor is turned on. For more details, see Section 3.2.2.

b. OBCAD (open cable detect), I/O

Signal for indicating an open A-cable or loss of IDC power. See Section 3.2.2 for more details.

3.3.3 Microprocessor Controller Logic

This portion of the IDC board interprets and acts on the Series-3200 Processor commands (e.g.; seek, read, write and format), causing the disk drives to perform specific operations or data transfers. It also controls the IDC interface circuitry between the SELCH/MUX bus and the disk files. Microprocessor control logic consists of twenty-two functional blocks:

1. Two 4-bit slice microprocessors
2. Control-store programmable read only memory (PROM) banks
3. Pipeline register
4. Microprogram sequencer
5. Map PROM
6. Condition code MUX
7. MUX inverter
8. Data latch
9. Map latch
10. Random access memory (RAM)
11. RAM control MUX
12. RAM control register
13. RAM-address counter for disk file transfer, and latch
14. RAM-address counter for DMA transfer, and latch
15. General-purpose data registers
16. DMA data registers
17. DMA control and bus data (BD) I/O control
18. Control latches
19. Error correction code (ECC) generation
20. Error correction control
21. Parallel-to-serial conversion
22. Serial-to-parallel conversion

The following Items describe these functional blocks and their associated I/O lines.

1. Two 4-Bit Slice Microprocessors

Serve as the 8-bit arithmetic logic unit (ALU) of the IDC. This ALU includes sixteen 8-bit ALU registers: each register consists of two 4-bit slices, with two address ports labeled A and B. Chapter 4 presents a more thorough description of this functional block. I/O lines are:

a. BD0:7 (bus data lines 0 through 7), I/O

Various data and controls to and from the microprocessor controller logic.

b. LBD0:7 (latched bus data Bits 0 through 7), input

Latched data (i.e.; temporarily stored data) from BD0:7. This data is used by the ALU as input.

c. A (A-register address bits), input

A 4-bit binary-coded value for selecting one of the sixteen ALU registers as the A-register. (Physically, A represents four lines: A0 through A3. See Appendix A for further description.)

d. B (B-register address bits), input

A 4-bit binary-coded value for selecting one of the sixteen ALU registers as the B-register. (Physically, B represents four lines: B0 through B3. See Appendix A for further description.)

e. I (ALU instruction bits), input

A 9-bit binary coded field for ALU instruction input. The first 3-bit value of this field yields the source of the ALU input data. The second 3-bit value gives a specific ALU instruction, arithmetic or logical. The third 3-bit value yields the destination for the resulting ALU output data. (Physically, I represents nine lines: I0 through I8. See Appendix A for further description.)

f. CONT (control), input

Two control bits: one for enabling output onto BD0:7, and one for arithmetic carry-in. (Physically, CONT represents two lines: CIN and POE. See Appendix A for further description.)

g. COND CODE (condition code), output

A 4-bit condition code associated with ALU instruction execution: overflow, sign bit, carry and zero result. (Physically, COND CODE represents four lines: OFLOW, SIGN, CARRY7 and F=0. See Appendix A for further description.)

2. Control Store PROM Banks

Consist of PROM for storing the IDC microcode, the internal IDC program which controls the microprocessor circuitry to provide controller operations. PROM is organized into 1024 (two banks of 512) 56-bit words. Throughout the following descriptions, these 56-bit words are referred to as microinstructions or microcode. I/O lines are:

a. PA0:8, SPA9 (program address lines 0 through 9), input

A 10-bit address from the microprogram sequencer for selecting one of the 1024 microcode locations.

b. 56 Lines (not labeled), output

A 56-bit word containing microcode as output to the pipeline register.

3. Pipeline Register

Provides pipeline storage of the next sequential microinstruction. I/O lines are:

a. 56 Lines (not labeled), input

A 56-bit word, from control store PROM, containing the next sequential microinstruction.

b. RAM0:7 (RAM address bits), output

An 8-bit address of a RAM location.

c. RAM CTL (RAM control), output

Lines for controlling RAM enable, read and write. (Physically, RAM CTL represents five lines: MWE, MCE, AE/OE, PZ and CNT. See Appendix A for further description.)

d. BDIO0:5 (bus data I/O control), output

A 6-bit code for controlling the source and destination of BD0:7 data and for controlling IDC operations like latching and ECC-register shifting. See Appendix A for further description of these controls.

e. A (A-register address bits), output

A 4-bit binary-coded value for selecting one of the sixteen ALU registers as the A-register. (Physically, A represents four lines: A0 through A3. See Appendix A for further description.)

f. B (B-register address bits), output

A 4-bit binary coded value for selecting one of the sixteen ALU registers as the B-register. (Physically, B represents four lines: B0 through B3. See Appendix A for further description.)

g. I (ALU instruction bits), output

A 9-bit binary coded field for ALU instruction input. The first 3-bit value of this field yields the source of the ALU input data. The second 3-bit value gives a specific ALU instruction, arithmetic or logical. The third 3-bit value yields the destination for the resulting ALU output data. (Physically, I represents nine lines: I0 through I8. See Appendix A for further description.)

h. CONT (control), output

Two control bits: one for enabling output onto BD0:7, and one for arithmetic carry-in. (Physically, CONT represents two lines: CIN and POE. See Appendix A for further description.)

i. COND MUX CTL (condition code MUX control), output

Four bits three of which select one of eight conditions to be output by the condition code MUX. The fourth bit controls the MUX inverter. (Physically, COND MUX CTL represents four lines: MA, MB, MC and MI. For further description see Appendix A.)

j. BRA0:9 (branch address bits), output

A 10-bit address serving as a possible microprogram branch address or as a count value for the microprogram sequencer.

k. SI0:3 (sequencer instruction bits), output

A hexadecimal value for one of sixteen sequencer instructions. See Appendix A for further description.

4. Microprogram Sequencer

Calculates the next address within control store PROM. It performs any one of sixteen next address calculations, including sequential, branch conditional and return conditional. I/O lines are:

a. SI0:3 (sequencer instruction bits), input

A hexadecimal value for one of sixteen sequencer instructions. See Appendix A for further description.

b. BRA0:9 (branch address bits), input

A 10-bit microprogram branch address or count value from the pipeline register.

c. BRA0:7 (branch address), input

An alternate 8-bit microprogram branch address or count value from the map PROM.

d. CC (condition code), input

A pass or fail condition code for one of eight possible conditions determined by MA:MC. See Appendix A. The microprogram sequencer uses CC for a next address calculation, e.g.; a conditional branch or conditional return.

e. PA0:8, SPA9 (program address lines 0 through 9), output

A 10-bit address for selecting one of the 1024 microcode locations in control store PROM.

5. Map PROM

Contains constant data used by the microcode program, and contains addresses of routines within control-store PROM. Map PROM is organized into 512 8-bit locations: 256 bytes for the routine addresses and 256 bytes for the constant data. During power-up, the second set of 256 bytes (containing the constant data) is copied into RAM.

Later, the first set of 256 bytes (containing a table of routine addresses) is used for vectoring to a particular microcode routine: on receiving an instruction from the processor, e.g.; read, write or format track, the IDC logic references this table, gets the address of the microroutine for executing that instruction, and vectors to the routine. I/O lines are:

a. LBD0:7 (latched bus data bits 0 through 7), input

   Latched BD0:7 data which will result in the map PROM outputting either constant data or a microroutine address.

b. BRA0:7 (branch address), output

   Either a constant value or a microroutine address. If BRA0:7 contain a constant, it goes to the map latch. If BRA0:7 contain a microroutine address, it goes to the microprogram sequencer.

6. Condition Code MUX

Provides the CC input to the microprogram sequencer. I/O lines are:

a. COND CODE (condition code), input

   A 4-bit condition code associated with an ALU instruction execution: overflow, sign bit, carry and zero result. (Physically, COND CODE represents four lines: OFLOW, SIGN, CARRY7 and F=0. See Appendix A for further description.)

b. COND MUX CTL (condition code MUX control), input

   Three bits for selecting one of eight conditions to be output by the condition code MUX. The selected condition is output as the CC to the microprogram sequencer. (Here, COND MUX CTL represents three lines: MA, MB and MC. See Appendix A for further description.)

c. CC (condition code), output

   Selected condition code sent to the microprogram sequencer, via the MUX inverter.

7. MUX Inverter

Passes the selected condition code to the microprogram sequencer, with or without inversion according to the received MI bit. I/O lines are:

a. MI (MUX inverter bit), input

The fourth bit of the COND MUX CTL output from the pipeline register. If the MI bit is set, the CC output is inverted; otherwise, the CC is passed as received from the condition code MUX.

b. CC (condition code), I/O

As input, CC is the selection of one of eight possible condition codes from the condition code MUX. As output, CC is in either true or complement form according to the MI input.

8. Data Latch

Latches BD0:7 data for input to either the ALU (the two 4-bit slice microprocessors) or the map PROM. I/O lines are:

a. BD0:7 (bus data lines 0 through 7), input

Various microprocessor bus data.

b. LBD0:7 (latch bus data bits 0 through 7), output

Data as input to the ALU or the map PROM.

9. Map Latch

Latches data constants output from the Map PROM and outputs this data onto BD0:7. I/O lines are:

a. BRA0:7 (constant data), input

Data constants from the map PROM. (At power-up, the map PROM must write data constants to the RAM.)

b. BD0:7 (bus data lines 0 through 7), output

Data constants written to the RAM.

10. Random Access Memory (RAM)

Stores data constants and buffers read/write data. RAM consists of 1024 8-bit locations. It is equally divided into four pages: Page 0, consisting of 256 bytes, holds tabularized data constants from the map PROM. Pages 1, 2 and 3 buffer data read from and written to one of the disk files; each of these pages holds one logical sector (256 bytes) for the IDC-formatted disk media. I/O lines are:

a. BD0:7 (bus data lines 0 through 7), I/O

Data bytes to and from various functional blocks throughout the microprocesssor control logic.

b. RAM0:7 (RAM address bits), input

An 8-bit address within a page of RAM memory. One of the two RAM-address counters generate this address; see Items 13 and 14 below.

c. RAM0:7 (RAM address bits), input

An 8-bit address within a page of RAM memory. Control store PROM generates this address in order to read a data constant.

d. A8, A9 (RAM page address lines), input

Two binary bits for selecting one of four pages in RAM. (Physically, A8 and A9 represent two lines: PAGE13 and PAGE23. See Appendix A for further description.)

e. R/W (read/write enable), input

Signal for selecting a RAM read operation or a RAM write operation over BD0:7. (Physically, R/W represents one line: WENB. See Appendix A for further description.)

f. CENB (chip enable), input

Signal for enabling RAM output onto BD0:7.

11. RAM Control MUX

Controls the multiplexing of I/O operations at the RAM. (See Item 10 above for a description of RAM organization.)

The RAM control MUX multiplexes simultaneous read operations at the RAM, as follows: During a read operation from a disk file, RAM first reads a logical sector from the disk file into page 1. If this operation is a multisector read, RAM also reads another logical sector into page 2. Once page 1 is filled with a logical sector, and the ECC circuitry validates the ECC, DMA transfer to the SELCH/MUX bus begins. This transfer occurs simultaneously with the filling of page 2, as directed by the RAM control MUX. The filling of pages 2 and 3, and pages 3 and 1, proceed in the same manner.

Likewise, the RAM Control MUX multiplexes simultaneous write operations at the RAM, as follows: During a write operation to a disk file, RAM first writes a logical sector from the SELCH/MUX bus into page 1. Once page 1 is filled with a logical sector, data transfer to the selected disk file may begin. While this transfer is in progress, page 2 is filled with an additional sector of DMA data from the SELCH/MUX bus. The filling of pages 2 and 3, and pages 3 and 1, proceed in the same manner.

In summary, the RAM control MUX directs the multiplexing of RAM operations for DMA and disk file I/O. This multiplexing ensures that these operations are performed simultaneously at their required speeds. I/O lines are:

a. RAM CTL (RAM control), input

   Control information required for multiplexing the DMA and disk file I/O. (Physically, RAM CTL represents five lines: MWE, MCE, AE/OE, PZ and CNT. See Appendix A for further description.)

b. A8, A9 (RAM page address lines), output

   Two binary bits for selecting one of the three buffering pages: page 1, 2 or 3. (Physically, A8 and A9 represent two lines: PAGE13 and PAGE23. See Appendix A for further description.)

c. R/W (read/write enable), output

   Signal for selecting a RAM read or RAM write operation over BD0:7. (Physically, R/W represents one line: WENB. See Appendix A for further description.)

d. CENB (chip enable), output

   Signal for enabling RAM output onto BD0:7.

12. RAM Control Register

Holds information necessary for generating the RAM page number, read/write control, and chip enable as described above in Item 11. I/O lines are:

a. BD0:7 (bus data lines 0 through 7), input

Input data related to the page number and control signals needed for I/O multiplexing at the RAM.

b. RAM CTL (RAM control), output

Control information required for multiplexing the DMA and disk file I/O. (Physically, RAM CTL represents five lines: MWE, MCE, AE/OE, PZ and CNT. See Appendix A for further description.)

13. RAM-Address Counter for Disk File Transfer, and Latch

Specifies the address of a RAM location written to or read from a disk file. The associated latch controls the counter output to the RAM0:7 lines.

a. BD0:7 (bus data lines 0 through 7), input

Value for determining the RAM page location from which data transfer shall occur.

b.2 RAM0:7 (RAM address bits), output

RAM memory location for the disk file transfer.

14. RAM-Address Counter for DMA Transfer, and Latch

Specifies the address of the RAM location written to or read from the SELCH/MUX bus. The DMA transfer is always 256 bytes, i.e.; 128 halfwords. The associated latch controls the counter output to the RAM0:7 lines.

a. CTL (control line), input

Signal for initializing the counter, which then counts up to 255 for the transfer of 256 bytes.

b. RAM0:7 (RAM address bits), output

RAM memory location for the DMA transfer.

15. General-Purpose Data Registers

Store various data to be sent to the SELCH/MUX bus, e.g.; status, sector addresses or RPS data. These registers also store various data received from the SELCH/MUX bus for RAM input, e.g.; a cylinder or head address. I/O lines are:

a. CTL'S (control lines), input

Three controls for determining whether general-register data is to be transmitted to the SELCH/MUX bus, received from the SELCH/MUX bus or enabled for output over BD0:7.

b. D08:15 (data bits 8 through 15), input

Byte of information from the SELCH/MUX bus.

c. GPD08:15 (general-purpose data), output

Register data to be sent to the SELCH/MUX bus.

d. BD0:7 (bus data lines 0 through 7, I/O

General-purpose data sent to and received from the microprocessor controller logic.

16. DMA Data Registers

Hold data received and transmitted between the SELCH/MUX bus and RAM. I/O lines are:

a. BD0:7 (bus data lines 0 through 7), I/O

DMA data transfered between RAM and the SELCH/MUX bus.

b. CTL'S (control lines), input

Ten control/timing signals for loading the registers and enabling them to output data to the applicable buses.

c. D00:15 (receive data bits 00 through 15), input

Halfword of data received from the SELCH/MUX bus, to be output to the RAM.

d. DATA00:15 (data bits 00 through 15), output

Halfword of data to be sent to the SELCH/MUX bus.

17. DMA Control and Bus Data (BD) I/O Control

Sets up and maintains DMA transfers, via the DMA Data Registers, between the SELCH/MUX bus and the RAM. I/O lines are:

a. CTL'S (control lines), input

Ten control/timing signals. These are also passed on to the DMA data registers.

b. BDIO0:5 (bus data I/O and controls), input

A 6-bit code that controls the source and destination for BD0:7 and provides numerous control signals. See Appendix A for further description.

c. CTL'S (control lines), output

Control for one of the operations selected by the decoding of BDIO0:5 input.

d. 3200 PTCL (3200 protocol), output

Control signals to the SELCH for the new high-speed SELCH protocol. (Physically, 3200 PTCL represents two lines: STCHK and CTLOPTC. See Appendix A for further description.)

18. Control Latches

Latches halfword data (e.g.; cylinder or head address) from the processor for subsequent input to the RAM. I/O lines are:

a. D00:15 (data halfword), input

Data halfword received over the SELCH/MUX bus from the processor.

b. CTL'S (control lines), input

Control/timing functions required for receiving halfword data from the processor.

c. BD0:7 (bus data lines 0 through 7), output

Halfword data latched from the processor and sent as bytes to the RAM.

19. Error Correction Code (ECC) Generation

Generates a 32-bit ECC for a disk file write or read operation.

With a write operation, ECC Generation receives serial write data from input line RSRO0, as described in Item 21 below. The circuitry then generates an ECC, which error correction control appends to the end of the 256 bytes of data written to the selected disk file.

With a read operation, ECC generation receives serial read data from input line RSR00, as described in Item 22 below. This input, consisting of 256-bytes of data and a 32-bit ECC, is serially shifted into the ECC generation circuitry. ECC generation then generates a new ECC from the 256 data bytes, and compares it with the read ECC. If the two ECCs match, the ECC is validated.

I/O lines are:

a. CTL'S (control lines), input

   Control/timing signals necessary for generating ECCs.

b. RSR00 (read/write serial data), input

   Serial data shifted into the ECC circuitry during a read or write operation. During a read operation, this serial input data also includes an ECC.

c. BD0:7 (bus data lines 0 through 7), output

   Error correction information output to the microprocessor logic whenever an ECC is not validated, i.e.; whenever an ECC is found erroneous.

20. Error Correction Control

Provides control circuitry necessary for ECC operations. I/O lines are:

a. RSR00 (read/write serial data), input

   Serial data shifted into the ECC circuitry during a write operation to a disk file.

b. CTL'S (control lines), I/O

   Control/timing signals necessary for generating ECCs and for detecting ECC errors.

c. WDATA (write data), output

   Serial data, along with a generated ECC, to be written to a disk file.

21. Parallel-to-Serial Conversion

Converts parallel RAM data from BD0:7 to serial data to be written to a disk file. This conversion circuitry applies only during disk file write operations, where data is written from the SELCH/MUX bus, via the RAM, to a disk file. I/O lines are:

a. CTL'S (control lines), input

Control/timing signals necessary for synchronizing the resulting serial write data to the disk file.

b. BD0:7 (bus data lines 0 through 7), input

Parallel data written from the RAM. The RAM originally received this data from the SELCH/MUX bus.

c. WSR (write serial data), output

Serial data to be written to a disk file. WSR output is passed, via serial-to-parallel conversion, as RSRO0 to Error Correction Control. There, a 32-bit ECC from ECC Generation circuitry is appended to the end of the 256 bytes of write data.

22. Serial-to-Parallel Conversion:

Converts serial disk file data from the SDATA input to parallel data, to be sent to the RAM. This conversion circuitry applies during disk file read operations, where data is read from a disk file, to the RAM, and to the SELCH/MUX bus. Also, during a write operation, this circuitry passes WSR input as RSRO0 output to error correction control and ECC Generation. I/O lines are:

a. SDATA (serial data), input

Serial data and ECC read from the disk file.

b. RSRO0 (read/write serial data), output

Same serial data and ECC as above, output to the ECC generation circuitry. More specifically, for a single disk file read operation, RSRO0 contains 256 bytes of data and a trailing 32-bit ECC. This data and ECC are input to ECC Generation circuitry which checks for errors. See Item 19 above.

c. BD0:7 (bus data lines 0 through 7), output

Parallel data sent to the RAM.

CHAPTER 4
MAINTENANCE

4.1 INTRODUCTION

Along with the table of mnemonics in Appendix A and the intelligent disk controller (IDC) board schematics, Chapter 4 presents detailed information necessary for troubleshooting the IDC board. Before reading this chapter, you should be thoroughly familiar with Chapter 3. For information pertaining to preventive maintenance on IDC disk files, see the list of related publications in Section 1.2.

4.2 MICROPROCESSOR/SEQUENCER CIRCUITRY

The heart of the IDC board is the microprocessor/sequencer circuitry. It provides, sequences, executes and routes the various microinstructions for interfacing a Series-3200 Processor and selector channel (SELCH)/multiplexor (MUX) bus with the IDC disk files. As shown in Figure 3-6, the microprocessor/sequencer circuitry consists of these functional blocks:

- Microprocessor (two 4-Bit microprocessor chips)
- Pipeline register
- Control store PROM
- Microprogram sequencer

Microinstructions are stored as part of the microprogram within the control store programmable read-only memory (PROM). Section 4.2.1 discusses these microinstructions.

The pipeline register latches each microinstruction (output from PROM) for input to the microprocessor and to the various functional blocks of the IDC controller logic.

The microprocessor, alternately referred to as the arithmetic logic unit (ALU), executes ALU instructions which are part of each microinstruction received from the pipeline register. Section 4.2.2 discusses the microprocessor.

The microprogram sequencer gives the IDC the capability of executing its stored microprogram from PROM. This capability classifies the IDC as intelligent. By acting on condition code, sequencer instruction and branch address inputs, the microprogram sequencer controls the execution sequence of the microprogram. Each 10-bit address output from the microprogram sequencer selects one of the 1024 microinstructions as the next instruction to be executed. Section 4.2.3 discusses the microprogram sequencer.

Section 4.2.4 describes the clock signals associated with microprocessor/sequencer operation.

Section 4.2.5 discusses general operation of the microprocessor/sequencer circuitry and presents examples of typical operations.

4.2.1 Microcode Instructions

A microcode instruction, or microinstruction, is a 56-bit output from control store PROM. Corresponding to these 56 bits are 56 output lines. See Figure 3-6, to the right side of the block diagram. As shown, going into the pipeline register from PROM are 56 lines (unlabeled). These same lines, which represent the 56 bits of a stored microinstruction, are output from the top of the pipeline register to these destinations: the random access memory (RAM) circuitry, the bus data Input/Output (I/O) control circuitry, the microprocessor (i.e.; the two 4-bit microprocessor chips), and the microprogram sequencer.

Table 4-1 lists the line mnemonics corresponding to the 56 microinstruction bits. These bits or lines are classified into five functional fields:

1. RAM address/control
2. Bus data I/O control
3. ALU address/control
4. Branch address/control
5. Microprogram sequencer

Sections 4.2.1.1 through 4.2.1.5 discuss the 56 output lines within these five fields.

TABLE 4-1. BIT DEFINITIONS OF THE 56-BIT MICROINSTRUCTION

BIT*	MNEMONIC	NAME	BIT*	MNEMONIC	NAME
55	BRA7	Branch Address Bit 7	26	CIN	Carry-In
54	BRA6	Branch Address Bit 6	25	POE	ALU Output Enable
53	BRA5	Branch Address Bit 5	24	MI	CC MUX Inverter Bit
52	BRA4	Branch Address Bit 4	23	RAM7	RAM Address Bit 7
51	BRA3	Branch Address Bit 3	22	RAM6	RAM Address Bit 6
50	BRA2	Branch Address Bit 2	21	RAM5	RAM Address Bit 5
49	BRA1	Branch Address Bit 1	20	RAM4	RAM Address Bit 4
48	BRA0	Branch Address Bit 0	19	RAM3	RAM Address Bit 3
47	SI3	Sequencer Instruction Bit 3	18	RAM2	RAM Address Bit 2
46	SI2	Sequencer Instruction Bit 2	17	RAM1	RAM Address Bit 1
45	SI1	Sequencer Instruction Bit 1	16	RAM0	RAM Address Bit 0
44	SI0	Sequencer Instruction Bit 0	15	BDIO5	Bus Data I/O Bit 5
43	A3	A-Register Address Bit 3	14	PZ	RAM Page Zero
42	A2	A-Register Address Bit 2	13	AE/OE	RAM Address Enable
41	A1	A-Register Address Bit 1	12	MCE	RAM Chip Enable
40	A0	A-Register Address Bit 0	11	MWE	RAM Write Enable
39	B3	B-Register Address Bit 3	10	CNT	RAM Page Counter Enable
38	B2	B-Register Address Bit 2	09	BRA9	Branch Address Bit 9
37	B1	B-Register Address Bit 1	08	BRA8	Branch Address Bit 8
36	B0	B-Register Address Bit 0	07	MC	CC MUX Selection Bit C
35	I8	ALU Instruction Bit 8	06	MB	CC MUX Selection Bit B
34	I7	ALU Instruction Bit 7	05	MA	CC MUX Selection Bit A
33	I6	ALU Instruction Bit 6	04	BDIO4	Bus Data I/O Bit 4
32	I5	ALU Instruction Bit 5	03	BDIO3	Bus Data I/O Bit 3
31	I4	ALU Instruction Bit 4	02	BDIO2	Bus Data I/O Bit 2
30	I3	ALU Instruction Bit 3	01	BDIO1	Bus Data I/O Bit 1
29	I2	ALU Instruction Bit 2	00	BDIO0	Bus Data I/O Bit 0
28	I1	ALU Instruction Bit 1			
27	I0	ALU Instruction Bit 0			

*MSB is bit 55; LSB is bit 00.

4.2.1.1 Random Access Memory (RAM) Address/Control Field

This field has thirteen bits. As shown in Figure 3-6, two outputs leave the top of the pipeline register and go to the RAM control circuitry: RAM address lines (RAM0:7) and RAM control (RAM CTL). RAM0:7 is an 8-bit address for selecting one of 256 locations within one of the four RAM pages. RAM CTL represents five control lines:

1. RAM address enable (AE/OE)

   A high on this line selects RAM0:7 from the pipeline register as the RAM address source. A low selects RAM0:7 from the RAM address counter as the address source.

2. RAM page counter enable (CNT)

   When high, this line enables the RAM page counter to increment to the next page.

3. RAM chip enable (MCE)

   This line enables the RAM for a read or write operation.

4. RAM write enable (MWE)

   This line enables RAM to be written to.

5. Page zero (PZ)

   This line selects RAM page zero.

4.2.1.2 Bus Data Input/Output (I/O) Control Field

This field has six bits: Bus data I/O and control bits (BDIO0:5). BDIO0:5 contain a 6-bit code for controlling I/O over the microprocessor bus BD0:7. Table 4-2 lists the BDIO0:5 codes and the corresponding BD0:7 contents. For additional information to interpret this table, see the table of mnemonics in Appendix A.

Notice that the MODE column of Table 4-2 specifies either a read, a write or a strobe. A read denotes BD0:7 source data going into the microprocessor or RAM. A write denotes BD0:7 destination data going out of the microprocessor, RAM or map PROM. A strobe denotes one of the numerous bus data control functions. See Section 4.2.4.2 for further detail.

TABLE 4-2. BDIO0:5 VALUES FOR MICROPROCESSOR BUS FUNCTIONS

BDIO0:5		MODE & TIMING	FUNCTION MNEMONIC	FUNCTION NAME	CONTENTS OF BD0:7 BITS*

** Register data I/O. See descriptions of corresponding mnemonics in Appendix A.
*** Bits BD7:2 associated with ESTBRA do not actually contain the specified mask data. However, the BD7:2 bits are ANDed with the specified mask mnemonics to enable status branches.
**** These entries indicate that the bit position is latched but not currently used.

4.2.1.3 Arithmetic Logic Unit (ALU) Address/Control Field

This field has nineteen bits. As shown in Figure 3-6, four outputs leave the top of the pipeline register and go to the microprocessor circuitry: A, B, CONT and I.

A-output represents four lines: A-register address bits (A0:3). A0:3 contain a binary value for selecting one of the ALU registers as the source A-register. Section 4.2.2 further discusses this selection.

B-output represents four lines: B-register address bits (B0:3). B0:3 contain a binary value for selecting one of the ALU registers as the source/destination B-register. Section 4.2.2 further discusses this selection.

CONT output represents two lines: Carry-in (CIN) and ALU output enable (POE). CIN is a microcode-generated carry input to the ALU. POE enables ALU output onto BD0:7. Section 4.2.2 further discusses these lines.

I output represents nine lines: ALU instruction bits (I0:8). I0:8 contain a 9-bit instruction for an ALU operation. The first three bits of this code, I0:2, denote the source of input data; the second three bits, I3:5, specify the particular ALU operation; and the third three bits, I6:8, denote the destination of results. See Tables 4-4 through 4-7 in Section 4.2.2 for detailed descriptions of I0:8.

4.2.1.4 Branch Address/Control Field

This field has ten bits: branch address bits (BRA0:9). BRA0:9 contain either a 10-bit branch address or a constant count value as input to the microprogram sequencer. These bits specify either the location of the next microinstruction to branch to or the count value for controlling microinstruction loop executions. Execution of a particular branch address depends on the microprogram sequencer field discussed below.

4.2.1.5 Microprogram Sequencer Field

This field has eight bits. As shown in Figure 3-6, two outputs leave the top of the pipeline register and go to the microprogram sequencer, via the condition code MUX and the MUX inverter. These outputs are: condition code MUX control (COND MUX CTL) and microprogram sequencer controls (CTL).

COND MUX CTL represents four lines: condition code MUX selection bits (MA:MC) and the CC MUX inverter bit (MI). MA:MC contain a 3-bit code that results in a condition code (CC) output, via the condition code MUX, to the microprogram sequencer. This CC output, along with BRA0:9, is used for a next address calculation. Table 4-3 gives the MA:MC possibilities; where necessary, see Appendix A for further description of the mnemonics. MI, the fourth bit of COND MUX CTL, inverts the CC output from the MUX inverter when required.

Sequencer instruction bits (SI0:3) contain a hexadecimal value for one of sixteen possible sequencer instructions to generate the next microinstruction address within PROM. Table 4-8 presents a detailed description of these bits.

TABLE 4-3. MA:MC VALUES FOR CC OUTPUT

MA:MC VALUE	CONDITION MNEMONIC	CONDITION NAME
0	CCMUXP	CC MUX Output
1	OFLOW	Overflow
2	SIGN	Sign Bit
3	CARRY7	Carry Bit 7
4	RSEL	Register Select
5	IPRY	Input Ready
6	SON	Latched Sync On
7	F=0	Function Equals Zero

* Condition Code (CC) output from the condition code multiplexer consists of one of the eight conditions selected by the octal value of the three bits, MA:MC. (MC is the most significant bit.) See Appendix A for further description of the selected conditions.

4.2.2 The 4-Bit Slice Microprocessors

Two identical 4-bit slice microprocessor chips are connected on the IDC board to form the 8-bit ALU circuitry. One chip handles the most significant four bits (MSBs) of each I/O byte, and the other handles the least significant four bits (LSBs). Figure 4-1 shows a functional block diagram of one 4-Bit slice microprocessor; for further information, see the block diagram of Figure 3-6. The following items discuss the functional blocks and I/O lines in Figure 4-1. Labeling in this figure is according to manufacturer's specification.

a. MicroRAM

This block, also referred to as local RAM, consists of sixteen 4-bit RAM locations. These are addressed by the A- and B-register address lines (A0:3 and B0:3). That is, A0:3 and B0:3 inputs determine which of the sixteen locations are read into the A- and B-Latches.

A0:3 and B0:3 inputs can specify the same address. Also, B0:3 specifies the RAM write location for data input via the RAM shift MUX.

b. A- and B-latches

These two latches hold output from the MicroRAM and serve as inputs to the R- and S-MUXs. Data is held in the A- and B-latches while CLK6 (see Section 4.2.4) is low, thereby avoiding any race condition.

c. R-MUX and S-MUX

These multiplexers are the two input ports to the ALU. As shown in Figure 4-1, the R-MUX passes input from either of two sources: latched bus data bits (LBD0:3 or LBD4:7, depending on whether the microprocessor is the less significant or more significant chip) or A-latch output. LBD0:7 input is also referred to as direct data. The S-MUX passes input from one of three sources: A-latch output, B-latch output, or Q-register output (Q0:3). In addition to the inputs just specified, the R- and S-MUXs can output a zero to the ALU.

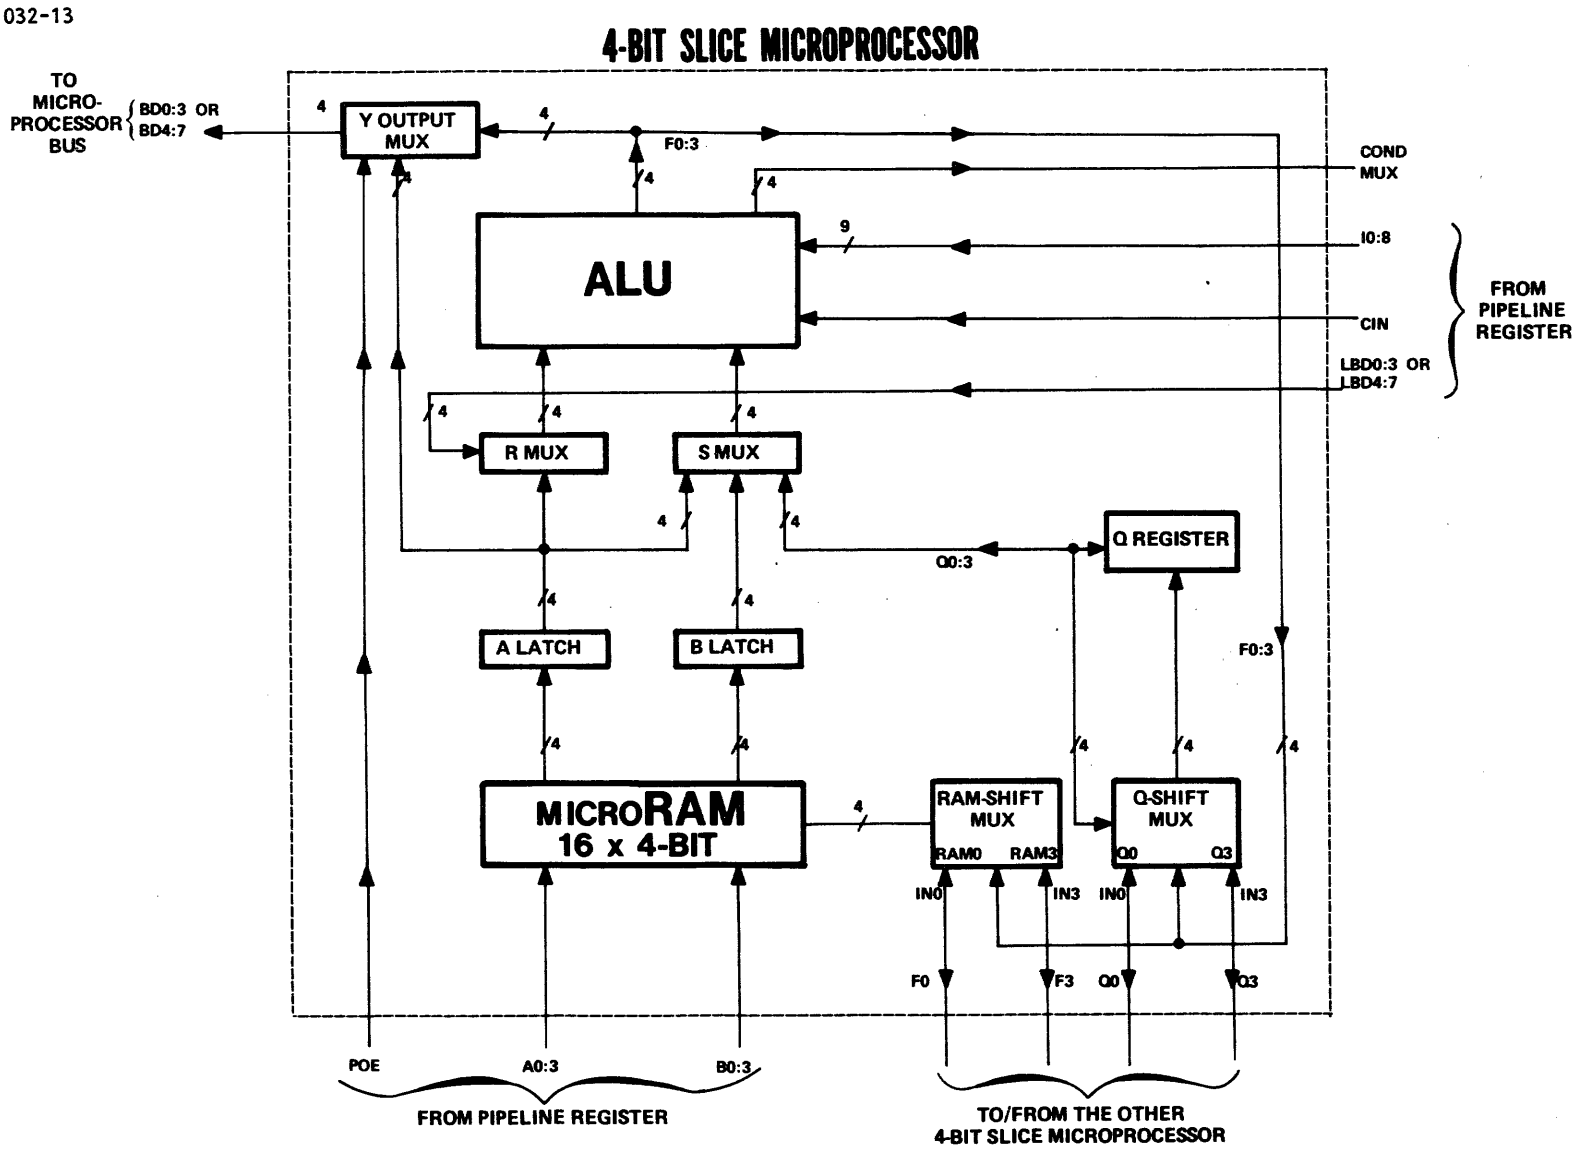

Figure 4-1 Block Diagram of the 4-Bit Slice Microprocessor

d. Q-register

The main purpose of the Q-register is to enable the double length shifts required by binary multiplication and division. Therefore, the Q-register receives, via the Q-shift MUX, both ALU output (F0:3) and its own output (Q0:3). Shifts are controlled by the ALU destination control bits I6:8; Table 4-7 specifies I6:8 values for up and down shifting.

The Q-register is also employed as a holding register or accumulator.

e. Q-shift MUX

This multiplexer receives F0:3 as input from the ALU and Q0:3 as input from the Q-register. Output to the Q-register can be shifted one bit in either direction, up or down or, not shifted at all.

The IN0/IN3 inputs and the Q0/Q3 outputs carry overflow bits resulting from an up or down shift operation. Table 4-7 presents further information on this operation.

f. RAM-shift MUX

This multiplexer receives F0:03 as input from the ALU. Output goes to the MicroRAM and, like the Q-shift MUX, this output can be shifted one bit in either direction, or not shifted at all.

The IN0/IN3 inputs and the F0/F3 outputs carry overflow bits resulting from an up or down shift operation. Table 4-7 presents further information on this operation.

g. Y-output MUX

This multiplexer receives input from either the AlU or the A-latch. When the ALU output Enable (POE) signal is active, low, the Y-output MUX outputs F0:3 or the A-register contents onto the microprocessor Bus (BD0:3 or BD4:7, depending on whether this microprocessor is the less significant or more significant chip).

Microprocessor output lines to BD0:7 are in the high-impedance state whenever POE is high.

h. ALU

Depending on the input of the ALU instruction bits (I0:I8), the ALU performs arithmetic or boolean functions. See Tables 4-4 through 4-7 for detailed information. The carry-in (CIN) input is generated by microcode to increase the number of possible functions. For the more significant ALU, CIN is the carry-out of the less significant ALU. Condition code (CC) output indicates the results of ALU instruction execution, i.e.; the execution of the I0:8 bits. It is a 4-bit condition code representing four lines: overflow (OFLOW), sign bit (SIGN), carry bit (CARRY7) and function equals zero (F=0). For further description of these four lines, see Appendix A.

4.2.2.1 Arithmetic Logic Unit Instructions From I0:8

ALU instructions are input to the ALU through nine lines: I0:8. (As previously discussed, an ALU instruction is part of the 56-bit microinstruction output from control store PROM; see Figure 3-6.) These nine bits determine data flow and control function. The first three bits, I0:2, select the input source to the ALU. The second three bits, I3:5, specify the ALU function to be performed. The third three bits, I6:8, select the destination for the results of the executed function. Tables 4-4 through 4-7 define the contents of I0:8, and Items 1 through 3 below discuss these bits.

1. ALU source selection with I0:2

   See Figure 4-1. As illustrated there, input to the ALU is from the R-MUX and S-MUX. Furthermore, as discussed earlier:

   a. Input from the R-MUX to the ALU can be one of three sources: LBD0:3/LBD4:7, A-latch data or zero.

   b. Input from the S-MUX to the ALU can be one of four sources: A-latch data, B-latch data, Q0:3 or zero.

   Consequently, the ALU has twelve possible input combinations, as shown below, where: A refers to A-latch, B refers to B-latch, D refers to direct data of LBD0:7, Q refers to Q-register and Z refers to zero.

   R-MUX Input: AAAA DDDD ZZZZ
   S-MUX Input: ABQZ ABQZ ABQZ

Since only three bits of the instruction code are available for specifying source input, only eight of the twelve combinations can be defined. However, since A and B can refer to the same MicroRAM location, the AA, AZ and DB combinations are redundant. Also, since zero/zero input is considered meaningless, ZZ is redundant. Consequently, I0:2 can specify all eight of the effective combinations. See Table 4-4.

TABLE 4-4. MICROINSTRUCTION BITS I0:2 FOR ALU SOURCE CONTROL

I0:2 VALUE			OCTAL CODE	ALU SOURCE INPUT		SOURCE MNEMONIC
I2	I1	I0		R-MUX*	S-MUX*	
0	0	0	0	A-Latch	Q-Register	AQ
0	0	1	1	A-Latch	B-Latch	AB
0	1	0	2	Zero	Q-Register	ZQ
0	1	1	3	Zero	B-Latch	ZB
1	0	0	4	Zero	A-Latch	ZA
1	0	1	5	LBD0:7	A-Latch	DA
1	1	0	6	LBD0:7	Q-Register	DQ
1	1	1	7	LBD0:7	Zero	DZ

* As represented in Figure 4-1, R-MUX and S-MUX are the two input ports to the ALU. Refer to Table 4-6 for I0:2 combinations with the I3:5 bits.

2. ALU Function Control with I3:5

Basically, I3:5 bits allow eight ALU functions to be specified three arithmetic and five boolean. See Table 4-5. However, since there are eight different ALU input combinations from I0:2, I3:5 actually allow more than just eight ALU functions. Also, the CIN bit permits additional operations. Table 4-6 shows all functions permitted with I3:5, I0:2 and CIN inputs.

TABLE 4-6. SOURCE-FUNCTION MATRIX FOR MICROINSTRUCTION BITS I0:5*

ALU FUNCTION BITS I3:5 (OCTAL VALUE)		ALU SOURCE INPUT BITS I0:2 (OCTAL VALUE) AQ (0)	AB (1)	ZQ (2)	ZB (3)	ZA (4)	DA (5)	DQ (6)	DZ (7)

* This table is a combination of Tables 4-4 and 4-5. If necessary, see these tables for further detail.

TABLE 4-7 MICROINSTRUCTION BITS I6:8 FOR ALU DESTINATION CONTROL*

I6:8 VALUE			OCTAL CODE	RAM SHIFTER IN/OUT		RAM FUNCTION		Q-SHIFTER IN/OUT		Q-REGISTER FUNCTION		COMMENTS
I8	I7	I6		RAM0	RAM3	SHIFT	LOAD	Q0	Q3	SHIFT	LOAD	
0	0	0	0	n/a	n/a	n/a	none	n/a	n/a	none	F to Q	Loads F0:3 to the Q-register.
0	0	1	1	n/a	n/a	n/a	none	n/a	n/a	n/a	none	Generates BD0:3/BD4:7 output only if POE control input is low.
0	1	0	2	n/a	n/a	none	F to B	n/a	n/a	n/a	none	Generates BD0:3/BD4:7 output directly from a MicrorAM A-register. F0:3 output is to a MicrorAM B-register.
0	1	1	3	n/a	n/a	none	F to B	n/a	n/a	n/a	none	F0:3 output is to a MicrorAM B-register.
1	0	0	4	F0	IN3	down	F/2 to B	Q0	IN3	down	Q/2 to Q	F0:3 output is down-shifted and input to a MicrorAM B-register: F0 output, resulting from the down-shift of the less significant MicroRAM, wraps around as IN3 input to the MSB of the more significant MicroRAM. Q-register output is down-shifted and again input to the Q-register: Q0 output, resulting from the down-shift of the less significant Q-register, wraps around as IN3 input to the more significant Q-register.
1	0	1	5	F0	IN3	down	F/2 to B	Q0	n/a	n/a	none	F0:3 output is down-shifted and input to a MicroRAM B-register as just discussed above.
1	1	0	6	IN0	F3	up	2xF to B	IN0	Q3	up	2xQ to Q	F0:3 output is up-shifted and input to a MicroRAM B-register: F3 output, resulting from the up-shift of the more significant MicroRAM, wraps around as IN0 input to the LSB of the less significant MicroRAM. Q-register output is up-shifted and again input to the Q-register: Q3 output, resulting from the up-shift of the more significant Q-register, wraps around as IN0 input to the less significant Q-register.
1	1	1	7	IN0	F3	up	2xF to B	n/a	Q3	n/a	none	F0:3 output is up-shifted and input to the MicroRAM B-register as just discussed above.

* Every I6:8 value generates a BD0:3/BD4:7 output, provided the POE input to the Y-output MUX is low. The letters n/a (non-applicable) denote a don't care combination where the associated output is in a high-impedance state. (Specifically, the shift pin is a TTL input internally connected to a 3-state output in the high-impedance state.) The terms up and down respectively refer to a shift up towards the MSB or a shift down towards the LSB.

4.2.3 Microprogram Sequencer

As its name implies, the microprogram sequencer controls the sequence of microinstruction execution. See the block diagram of Figure 3-6. To output the 10-bit address (PA0:8, SPA9) to PROM for the next microinstruction to be executed, the microprogram sequencer receives three inputs:

1. Branch Address Bits (BRA0:9)

2. Condition Code (CC)

3. Sequencer Instruction Bits (SI0:3)

From the pipeline register, BRA0:9 supplies a 10-bit branch address for the next microinstruction to be executed by IDC controller circuitry. BRA0:9 can address all of the 1024 56-bit locations within control store PROM. The actual branch address, if any, depends on the CC and SI0:3 inputs. Alternately, instead of a branch address, BRA0:9 can supply a count value for iterations (repetitive executions) of a microinstruction loop.

CC supplies one of eight condition code tests used by the microprogram sequencer for a next address calculation. Table 4-3 describes the MA:MC bits associated with the CC.

SI0:3 specify one of sixteen possible sequencer instructions. These are described later in Section 4.2.3.1. (To more easily understand the following discussions, you might want to refer there now and scan Table 4-8 to gain an overview of these instructions.)

Figure 4-2 on the next page shows a functional block diagram of the microprogram sequencer. The following items discuss the functional blocks and I/O lines shown in the figure.

a. Address/down-counter register and zero detector

   This register functions either as an address register or a down counter. As an address register, it functions as a holding register to temporarily store a branch address from BRA0:9. As a down counter, it controls microinstruction loop iterations. Specifically, BRA0:9 loads the register with a count value of one less than the wanted number of iterations. Before each successive execution of a microinstrution loop, the zero detector examines the count for a zero value; if not equal to zero, the count is decremented and the loop executes. This operation continues until a zero is detected, terminating loop execution. [The decrement repeat loop (DRL), decrement repeat instruction (DRI), and three-way branch (TWB) sequencer instructions in Table 4-8 use the register as a down counter.]

The address/down-counter register is loaded with either of two sequencer instructions from Table 4-8: load counter (LDCT) or push conditional load (PCL). LDCT explicitly loads the down counter register with a count value from BRA0:9. PCL conditionally loads the address register with a branch address from BRA0:9.

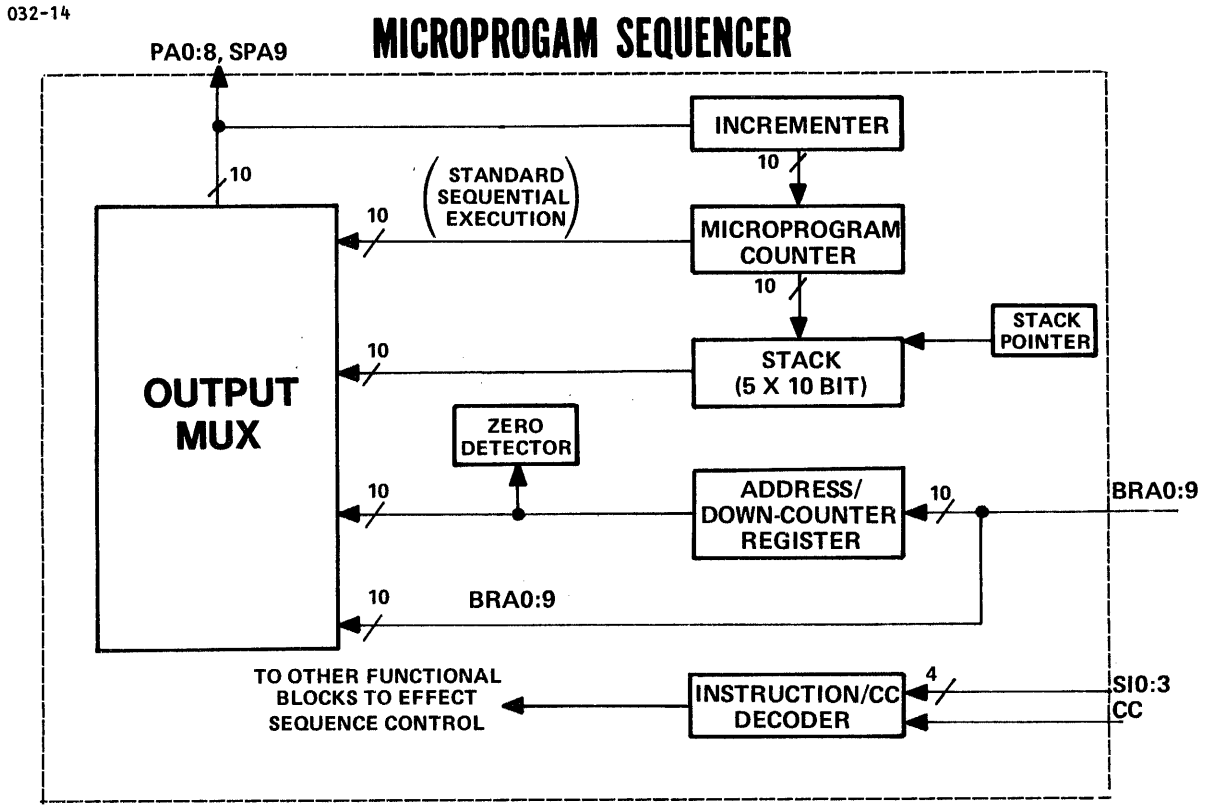

Figure 4-2 Block Diagram of the Microprogram Sequencer

b. Incrementer

The 10-bit address from the output MUX is always input to the incrementer which increments the address by a value of one before passing it to the microprogram counter.

c. Microprogram counter

Once incremented, the 10-bit address from the output MUX is stored in the microprogram counter. During standard sequential microinstruction execution, this functional block supplies the output MUX with the address of the next microinstruction to be executed by the IDC logic.

d. 5x10 bit stack with stack pointer

This functional block stores return addresses for subroutine calls. It is a 5-level first-in/first-out (FIFO) stack with a stack pointer pointing to the top address. Return address inputs and outputs of this stack are performed by push and pop operations from the sequencer instructions. A push operation increments the stack pointer and pushes an address from the microprogram counter to the top-of-stack. (Should the stack be full when an address is pushed in, the current address at top-of-stack is overwritten and lost.) A pop operation decrements the stack pointer and pops the formerly current return address from the top-of-stack. [Push operations are performed by the CC, push conditional load (PCL) and conditional call 2 places (CC2) sequencer instructions. Pop operations are performed by the DRL, conditional return (CR), conditional jump and pop (CJP), loop on fail (LOOP) and TWB sequencer instructions.]

e. Instruction/CC decoder

This functional block receives the sequence instruction bits (SI0:3) and CC input that control other-than-standard sequencing of microinstruction execution. Section 4.2.3.1 discusses the sixteen possible sequencer instruction input from SI0:3. For information pertaining to the CC bit, see Table 4-3.

With the SI0:3 and CC inputs, the instruction/CC decoder outputs the sequence control signals to numerous points throughout the microprogram sequencer to effect sequence control.

f. Output MUX

Depending on the sequencer instruction received via SI0:3, the output MUX selects an address from one of four sources:

1. BRA0:9 (direct data)

2. Address Register

3. Stack

4. Microprogram Counter

For specific source inputs, see the list of sequencer instructions in Table 4-8.

4.2.3.1 Sequencer Instructions from SI0:3

Sequencer instructions are input to the microprogram sequencer through four lines: SI0:3. (As discussed in Section 4.2.1.5, SI0:3 are part of the 56-bit microinstruction output from control store PROM.) These four lines specify a hexadecimal code for one of sixteen sequencer instructions.

Table 4-8 lists and describes these instructions. By briefly scanning the descriptions in this table, you can see that a conditional pass or fail test is used frequently to effect various operations. A pass condition occurs when the CC input is low; a fail condition occurs when CC input is high.

TABLE 4-8. SI0:3 INPUT TO MICROPROGRAM SEQUENCER

SI0:3 VALUE	INSTRUCTION NAME (MNEMONIC)	DESCRIPTION
0	Jump-to-Zero (JZ)	Used at power-up or initialization. As a result of this instruction, the address of the next microinstruction is zero, and the stack pointer resets to zero. The microprogram counter now holds an address value of 0.
1	Conditional Call (CC)	A conditional call to a subroutine, depending on whether a condition passes or fails. If the condition passes, contents of the microprogram counter are pushed onto the stack, and the microinstruction addressed by BRA0:9 is executed by the IDC logic. If the condition fails, the next sequential instruction from the microprogram counter is executed by the IDC logic.
2	Unconditional Jump (JT)	An unconditional jump to the start of a new microprogram. As a result of this instruction, the microinstruction addressed by BRA0:9 is executed, and the microprogram counter is loaded with the BRA0:9 address plus one.
3	Conditional Jump Microcode (CJ)	A conditional jump or branch in microinstruction execution, depending on whether a condition passes or fails. If the condition passes, the microinstruction addressed by BRA0:9 is executed. If the condition fails, the next sequential instruction from the microprogram counter is executed.
4	Push, Conditional Load (PCL)	Used primarily to set-up loop execution. It causes the contents of the microprogram counter to be pushed onto the stack. Then the condition is tested to determine if the down counter is to be loaded. If the condition passes, BRA0:9 contents are loaded into the down counter to become the count value. If the condition fails, the down counter is not loaded.
5	Conditional Call, 2 Places (CC2)	A conditional call to one of two subroutines, depending on whether a condition passes or fails. After the contents of the microprogram counter are pushed into the stack, the condition is tested. If it passes, the subroutine addressed by BRA0:9 is executed, i.e.; the output MUX selects the BRA0:9 address. If the condition fails, the subroutine addressed by the address register is executed, i.e.; the output MUX selects the output of the address register.
6	Conditional Jump Map (CMAP)	A conditional jump or branch based on the input of BRA0:7 from map PROM. The branch depends on a conditional test. If it passes, the next microinstruction addressed by BRA0:7 is executed. If it fails, the next sequential instruction from the microprogram counter is executed.
7	Conditional Jump, 2 Places (CJ2)	A conditional jump or branch to one of two locations, depending on the conditional test results. (This instruction is like CC2 described above, but without a stack push.) If the condition passes, the microinstruction addressed by BRA0:9 is executed. If it fails, the microinstruction at the address held by the address register is executed.
8	Decrement, Repeat Loop (DRL)	Repeats a microinstruction loop until down counter contents equal zero. Stack contains the starting address of the microinstruction loop. Before this instruction can execute, the down counter must have been loaded with a

TABLE 4-8. SI0:3 INPUT TO MICROPROGRAM SEQUENCER (Continued)

SI0:3 VALUE	INSTRUCTION NAME (MNEMONIC)	DESCRIPTION
		value of one less than the wanted number of iterations. Before each loop, the down counter contents are examined: if contents do not equal zero, the down counter decrements and the address at top-of-stack executes; or, if contents equal zero, the stack pops and the next sequential instruction from the microprogram counter executes.
9	Decrement, Repeat Instruction (DRI)	Repeats execution of a microinstruction until the down counter contents equal zero. BRA0:9 contain the address of the microinstruction to be repeatedly executed. Before this instruction can execute, the down counter must have been loaded with a value of one less than the wanted number of iterations. Before each repetitive execution, down counter contents are examined: if contents do not equal zero, the down counter decrements and the BRA0:9 address executes; if contents equal zero, the next sequential instruction from the microprogram counter executes.
A	Conditional Return (CR)	A conditional return from a subroutine to the microinstruction following the call to that subroutine. The return depends on a pass or fail condition. If the condition passes, the microinstruction given by the stack Address is executed. If it fails, the next sequential instruction of the subroutine loop is executed, i.e.; the output MUX takes the microinstruction address from the microprogram counter.
B	Conditional Jump and Pop (CJP)	A conditional loop termination with stack maintenance, depending on conditional testing. If the test passes, the stack pops and the microinstruction addressed by BRA0:9 executes. If it fails, the next sequential microinstruction from the microprogram counter executes.
C	Load Counter (LDCT)	Loads the down counter with a count from BRA0:9 for subsequent loop iteration. It then executes the next sequential microinstruction from the microprogram counter.
D	Loop on Fail (LOOP)	Causes a loop to be executed for failure of a conditional test. That is, if the test fails, the microinstruction addressed by the contents of stack is executed. If the test passes, the stack pops and the microinstruction addressed by the microprogram counter executes.
E	No Operation (NOP)	A default instruction resulting in an increment of the microprogram counter contents and the execution of the next sequential microinstruction from the microprogram counter.
F	Three-Way Branch (TWB)	A conditional loop instruction that permits a branch to three possible microinstructions. Before TWB executes, the down counter is loaded with a count value, and the stack has a branch address pushed in. During TWB execution, the down counter value decrements by one and a conditional test occurs. If the test passes, the next sequential microinstruction addressed from the microprogram counter executes; the stack then pops. If the test fails, the down counter contents are examined: if contents do not equal zero, the microinstruction addressed by BRA0:9 executes and the stack pops.

4.2.4 Intelligent Disk Controller (IDC) Operational Cycle

The IDC is a sequential state machine with a 16MHz clock as the basic timing signal. All other timing signals are either divisions of the 16MHz clock or summations of divisions. See the IDC schematics (sheet 19, grid coordinates B and 2). This sheet shows the 16MHz oscillator of the IDC. Output from this oscillator is the OSC signal from which the other clock signals, also shown on sheet 19, are derived. For brief descriptions of the clock signals shown on this sheet, see the table of mnemonics in Appendix A.

An IDC operational cycle is 375ns, made up of six negative-going clock phases of 62.5ns. Figure 4-3 illustrates this basic system timing. The following sections describe the IDC operations occurring for the operational phases of the IDC cycle.

4.2.4.1 Intelligent Disk Controller (IDC) Instruction Decoding Phase (CLK1)

At the falling edge of CLK1, the microprocessor (the two 4-Bit slice microprocessors) and the microprogram sequencer clock-in their respective fields of the 56-bit microinstruction. More specifically, the microprocessor clocks-in the ALU instructions from I0:8, and the microprogram sequencer clocks-in the sequencer instructions from SI0:3. At the rising edge of CLK1, instruction decoding finishes. (Although there appears to be a conflict in the figure between the active CLK1 and the direct memory access (DMA) bus low phases, internal decoding times associated with these phases absorb the contention.)

4.2.4.2 Intelligent Disk Controller (IDC) Instruction Cycle

As shown in Figure 4-3, the IDC instruction cycle consists of three phases:

1. Interal IDC Operation

2. DMA Bus High

3. DMA Bus Low

The following Items discuss these phases of the instruction cycle.

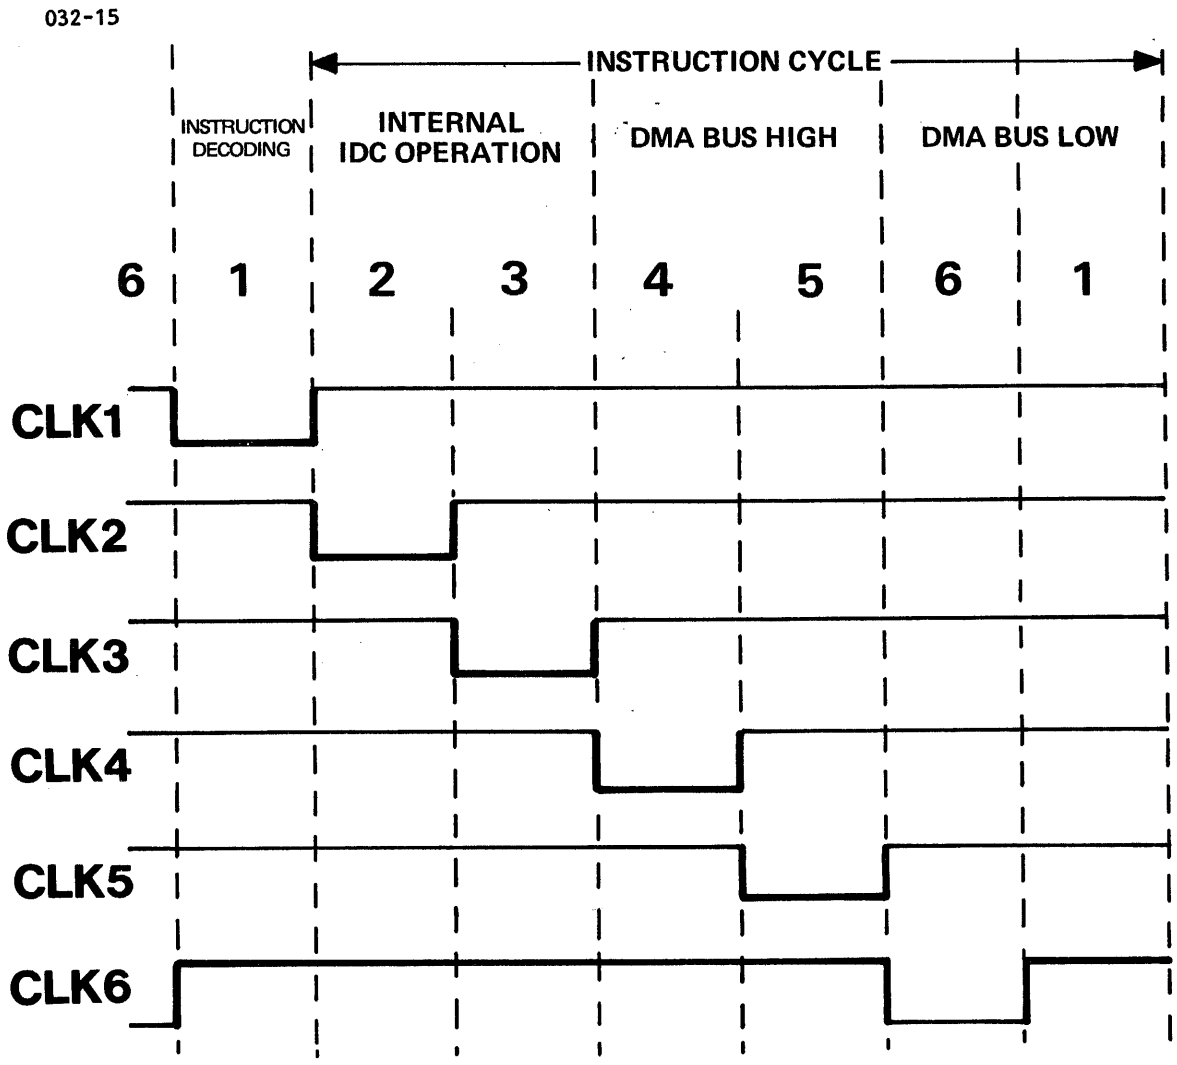

Figure 4-3 IDC Operational Cycle

1. Internal IDC Operation

This phase, occurring during CLK23 (summation of CLK2 and CLK3), encompasscs IDC operations not directly related with a DMA transfer. During CLK23, the IDC RAM circuitry may be written or read with disk data. Also during CLK23, BDIO0:5 functions are active. These functions control the source and destination of BD0:7 data and provide numerous control signals.

NOTE

As shown in Table 4-2, under the MODE column, each bus function is a read, a write or a strobe. A read signifies a data source; a write, a destination; and a strobe, a control signal.

The BD0:7 bus source, as determined by BDIO0:5, can be the serial-to-parallel converter, the general-purpose data register, etc., as illustrated in Figure 3-6. During CLK23, the selected source data goes to the microprocessor/sequencer circuitry or to the RAM. The internal destinations and control strobes are active during CLK3. A destination can be the RAM address counter, the disk data bus, the disk control tag or DMA circuitry. If the BDIO0:5 function is a strobe, it performs one of the numerous control functions listed in Table 4-2.

2. DMA Bus High, and

3. DMA Bus Low

All DMA transfer is in halfword mode. Therefore, to transfer a halfword to/from the SELCH/MUX bus, two accesses with the IDC RAM circuitry are required: one access writes or reads the more significant (high) byte to or from RAM, and the other access writes or reads the less significant (low) byte to or from RAM.

If the DMA transfer is to the IDC, the IDC lines D00:15 receive a halfword from SELCH. IDC then stores this halfword into the DMA data register. (See Figure 3-6.) Thus, during CLK45 (sum of CLK4 and CLK5 phases), the high byte of data from the DMA data register is written to RAM. And, during CLK61 (sum of CLK6 and CLK1 phases), the low byte of data from the DMA data register is written to RAM.

If the DMA transfer is from the IDC, then the IDC lines D00:15 send a halfword of data to SELCH. As above, this data is first stored in the DMA data register. Thus, during CLK45 and CLK61 respectively, the high and low bytes of data are read to the DMA data register from RAM.

As evident from the preceding paragraphs, the IDC can simultaneously perform instruction execution and DMA transfer during one 375ns operational cycle. In addition, during the internal IDC operational phase, the IDC can write or read a byte of data to or from a disk file. Consequently a DMA transfer to or from a disk file, via the IDC controller logic, does not need IDC microprogram intervention until the transfer ends. Stated in broader terms, one sector of data can be written to or read from a

disk file while, at the same time, a sector of data is transferred to or from the SELCH. During these simultaneous transfers, the microprocessor controller logic checks for track boundaries and DMA statuses.

4.2.5 Microprocessor/Sequencer Operation

At the start of an IDC operational cycle, with CLK6 going high, the ALU instructions on I0:8 and the sequencer instructions on SI0:3 are latched, respectively, into the microprocessor and the microprogram sequencer. Concurrent with the latching of these inputs, the next 56-bit microinstruction is latched into the pipeline register.

The I0:8 and SI0:3 instructions decoded during the CLK1 phase are executed during the CLK23 phase. Also during CLK23, BDIO0:5 contain a value whenever a microinstruction requires bus data I/O. When a data transfer from the microprocessor onto BD0:7 is required, BDIO0:5 determines either a source or a destination, but not both. See Table 4-2. If BDIO0:5 determine a data source (read mode), the destination is the IDC RAM or the A/B registers of the ALU. If BDIO0:5 determine a destination (write mode), the source is RAM, the ALU or the map PROM. Instead of determining a source read or a destination write, BDIO0:5 can specify a control strobe.

The actual microinstruction latched into the Pipeline Register, as discussed in Section 4.2.3, depends on the CC and SI0:3 inputs and, depending on the particular sequencer instruction from SI0:3, the BRA0:9 input. These inputs alter the normal sequence of microinstruction execution. Normally, microinstructions are executed from sequential PROM locations unless the CC and SI0:3 inputs determine a branch address.

The following items present three examples of typical microprocessor/sequencer operation.

1. Example 1

   Objective:

   Illustrate ALU-RAM interaction by adding the contents of an IDC RAM location to the contents of a microprocessor B-register.

Initial Conditions:

a. I0:8 contain a value of 502. From Tables 4-4 through 4-7 and Figure 4-1. A01:31 specifies register 4; B01:31 specifies register 4.

   - 5 denotes an R-MUX source of lBD0:7 and an S-MUX source of A-latch, which specifies MicroRAM register 4.
   - 0 denotes an ADD function of R-MUX input and S-MUX input.
   - 3 denotes an output over BD0:7 and a load of the same output to a MicroRAM B-register.

b. RAM0:7 specify RAM address 87, the contents of which are to be added to B-register 4.

c. SI0:3 contain a value of X'E' for NOP.

d. BDIO0:5 contain a value of X'00' for NOP.

e. BRA0:9 has no address.

Operational Sequence:

1. During CLK1, the microprocessor decodes I0:8.

2. During CLK23, these RAM controls are asserted: RAM page address bits (PAGE13,23) and RAM chip enable (CENB). These assertions result in the contents of RAM location 87 being read into BD0:7 as LBD0:7 input to the microprocessor.

3. During CLK23, according to the I0:8 value of 503, the microprocessor adds LBD0:7 input data to B-register 4.

2. Example 2

Objective:

Illustrate how the microprocessor/sequencer circuitry performs a branch within the microprogram.

Initial Conditions:

a. I0:8 has a value of 001. From Tables 4-4 through 4-7 and Figure 4-1:

- 0 denotes an R-MUX source of A-latch and an S-MUX source of B-latch.
- 0 denotes an ADD function of R-MUX input and S-MUX input.
- 1 denotes only an output onto BD0:7 from the ALU should POE be active.

b. POE input is inactive, inhibiting BD0:7 output from the ALU. Hence, the I0:8 instruction is effectively a NOP.

c. SI0:3 has a value of X'3' for a conditional jump (CJ).

d. BRA0:9 specify PROM address 34 as the branch address for the conditional jump.

e. CC is low to indicate a pass condition for RSEL.

Operational Sequence:

1. During CLK1, I0:8 and SI0:3 are decoded.

2. During the entire instruction cycle, RSEL is active (i.e.; CC is enabled with a low) and BRA0:9 specifies the address.

3. During CLK23, the microprogram sequencer sees an enabled CC input and executes the SI0:3 input. The resulting 10-bit address output from the microprogram sequencer causes a PROM microprogram branch to address 34.

3. Example 3

Objective:

Illustrate how BDIO0:5 lines put data onto the BD0:7 bus and into a MicroRAM B-register.

Initial Conditions:

a. BDIO0:5 has a value of X'0A' for an EDS signal to enable disk status.

b. I0:8 has a value of 543. From Tables 4-4 through 4-7 and Figure 4-1, A01:31 specifies register 3; B01:31 specifies register 3.

- 5 denotes an R-MUX source of LBD0:7 and an S-MUX source of A-latch, which specifies ALU register 3.
- 4 denotes an AND function of R-MUX input and S-MUX input.
- 3 denotes a load function of the resulting F0:F3 to a MicroRAM B-register.

c. SI0:3 have a value of X'E' for a NOP.

d. RAM0:7 have no address.

e. BRA0:9 have no address.

Operational Sequence:

1. During CLK1, the microprocessor decodes ALU instruction 543.

2. During CLK23, the BDIO0:5 function of EDS causes the contents of the disk file status register to be output onto BD0:7 and to be input to the microprocessor through LBD0:7.

3. During CLK23, execution of the ALU instruction ANDs two values: the disk status input from LBD0:7 and the contents of A-register 3. The ANDed value is then stored into MicroRAM B-register 3.

4.3 SELECTOR CHANNEL (SELCH)/MULTIPLEXOR (MUX) BUS INTERFACE

This portion of the IDC board interfaces the SELCH/MUX bus of a Series-3200 Processor with the IDC controller logic. The bus interface works with the microprocessor/sequencer logic in generating the commands, data and control sequences necessary for disk file I/O. I/O through the SELCH/MUX bus is either programmed or DMA. Section 4.3.1 discusses programmed I/O, and Section 4.3.2 discusses DMA I/O. For supplemental information on signal flow and mnemonics within these two sections, refer to the IDC block diagram of Figure 3-6, the table of mnemonics of Appendix A, and the 23 IDC schematic sheets.

4.3.1 Programmed Input/Output (I/O)

The SELCH/MUX bus interface supports the standard addressing functions:

- IDC or disk file address (ADRS)
- Receive acknowledgment (RACK)

As illustrated in Figure 3-6, the IDC receives an ADRS0 signal into the control line receivers. The controller address/file address compare and select circuitry uses ADRS0 for the address comparison and selection. If the address input through D08:15 pertains to this IDC or to an attached file, either equals controller (=CONT) or equals file (=FILE) is output accordingly. This output goes to the function encoding circuits discussed later.

A received RACK0 signal, if applicable to this IDC, results in the bus interface gating the IDC address or a disk file address to the processor. That is, the controller address (CA8:15) or the file address (FA8:15) is input to the data MUX, where it is gated and output to the processor via the data transceivers. If this IDC has no interrupt pending, RACK0 is passed on out as TACK0.

In addition to the two addressing functions described above, the SELCH/MUX bus interface supports the four standard bus I/O functions:

- Status request (SR)
- Output command (OC)
- Data request (DR)
- Data available (DA)

As illustrated in Figure 3-6, the IDC receives an SR0, OC0, DR0 or DA0 signal into the control line receivers, where they are output to the control line latches. The latched signal is then output to the function encoding circuits, which also receive the =CONT or =FILE input from the controller address/file address compare and select circuitry. The encoding circuits AND the received inputs to generate an encoded (octal) signal over the IDC function lines (FUNC0:2). Table 4-9 lists the eight bus functions associated with FUNC0:2.

The assertion of one of the FUNC0:2 functions enables the register select (RSEL) signal from the function encoding circuits. During the microprocessor/sequencer idle loop, microcode monitors RSEL. On finding RSEL enabled, the microcode acts on the encoded function, along with any associated input data, and performs the necessary operations. Afterwards, microcode responds with a controller sync (CONTSYNC) or file sync (FILESYNC) to indicate successful completion of the received bus I/O function.

TABLE 4-9. FUNC0:2 VALUES FOR ENCODED MUX BUS FUNCTIONS*

FUNC0:2 VALUE	FUNCTION MNEMONIC	FUNCTION NAME
0	ILDR	Idle Controller Data Request
1	ILDA	Idle Controller Data Available
2	ILSR	Idle Controller Status Request
3	CLOC	Controller Latched Output Command
4	FLDR	File Data Request
5	FLDA	File Data Available
6	FLSR	File Status Request
7	FLOC	File Output Command

* FUNC0:2 output is an octal value corresponding to one of the eight functions. (FUNC2 is the most significant bit.) See Appendix A for further description of the specified mnemonics.

Three of the bus functions SR0, DR0 and RACK0 require the IDC to respond with output data to the processor. MUX control bits (MUX13,23) select the particular register whose contents are to be transferred through the data transceivers. (See Appendix A for a description of these bits.) The enable MUX Output (EBLOUT) signal goes active to transmit this data. However, to ensure sufficient time for the register contents to be propagated through the data MUX, EBLOUT goes active 50ns after MUX13,23.

4.3.2 Direct Memory Access (DMA) Input/Output (I/O)

Microprocessor/sequencer microcode initiates DMA I/O, a halfword transfer, by generating DMA start (DMASTRT). If the transfer is a read operation from IDC to SELCH, IDC RAM circuits are read in two sequences:

1. Load high byte (LDHIBYT) loads the more significant RAM byte into the DMA register (chip 6F, sheet 5).

2. Load low byte (LDLOBYT) loads the less significant RAM byte into the other DMA register (chip 5F, sheet 5).

Once the RAM halfword is at the DMA registers, SELCH transfer (SELCHXFR) starts the DMA transfer over the SELCH/MUX bus.

If the transfer is a write operation from SELCH to IDC, the SELCHXFR signal first causes the received halfword to be loaded into the DMA registers (Chips 7J and 5J, sheet 5). Then:

1. Read high byte (RDHIBYT) loads the more significant SELCH byte into RAM.

2. Read low byte (RDLOBYT) loads the less significant SELCH byte into RAM.

Proper synchronization between SELCH and IDC for I/O is established by two DMA transfer flip-flops (chip 17J, sheet 7). During the read operation from RAM to SELCH, these flip-flops ensure the sequential activation of the RAM and DMA transfer controls, as follows: RAMXFR, DMAXFR, RAMXFR, ... The less significant 17J flip-flop is initially set high by IDC read (READ) to establish this sequence. During the write operation from SELCH to RAM, the flip-flops ensure the sequential activation of the DMA and RAM transfer controls, as follows: DMAXFR, RAMXFR, DMAXFR, ... The less significant 17J flip-flop is initially set low by IDC write (WRITE) to establish this sequence.

Before any disk file read/write operation, the processor performs these operational steps to position the disk read/write heads to the proper track and to select a specified sector:

1. Writes the specified cylinder number to the selected disk file.

2. Issues a seek command to the selected disk file.

3. Writes the specific head number to the selected disk file.

4. Issues a set head command to the selected disk file.

5. Writes the starting sector number to the IDC.

See Section 4.4 for further discussion of the above operations.

Sections 4.3.2.1 and 4.3.2.2 futher discuss the DMA read and write operations.

4.3.2.1 Direct Memory Access (DMA) Read Operation

Steps 1-10 below present the sequence of operations occurring with a DMA read, i.e.; a read of a data sector from a disk file via IDC to SELCH. Figure 4-4 shows the timing signals involved with a DMA read operation; see Appendix A for further description of the mnemonics there.

1. IDC receives a read command (a CMD0 function along with associated input data) from the processor. IDC then reads a previously specified sector into RAM page 1.

2. IDC receives a SELCH DR0 function.

3. Microprocessor/sequencer microcode then asserts DMA Start (DMASTRT).

4. DMASTRT assertion sets the DMA go (DMAGO) flip-flop and line, and resets the last word (LASTWRD) flip-flop. DMAGO starts the DMA transfer from RAM (i.e.; RAMXFR goes active).

5. The delayed DMA go (DDMAGO) line ensures that the two bytes read from RAM are stored in the DMA registers before being transferred to SELCH. During the RAMXFR operation, LDHIBYT loads the even RAM location of one byte to the DMA register; LDLOBYT loads the odd RAM location of one byte to the other DMA register.

6. To start the transfer to SELCH, provided a DR is asserted from SELCH, these signals go active: SELCHXFR, DMAXFR and XFERSYNCH. RAMXFR goes inactive.

7. A sync return (SYN) is output to SELCH after successful completion of the SELCH DR function.

8. SELCHXFR remains asserted after the SYN output to prevent another DMA operation, just yet, for another SELCH DR0 reception. XFRSYNCH, DMAXFR and SYN go inactive.

9. Transfer done (XFRDONE) is asserted once the IDC completes another RAM transfer, inactivating SELCHXFR.

10. RAM transfer repeats, starting at step 6 above, for each additional SELCH DR0 function received.

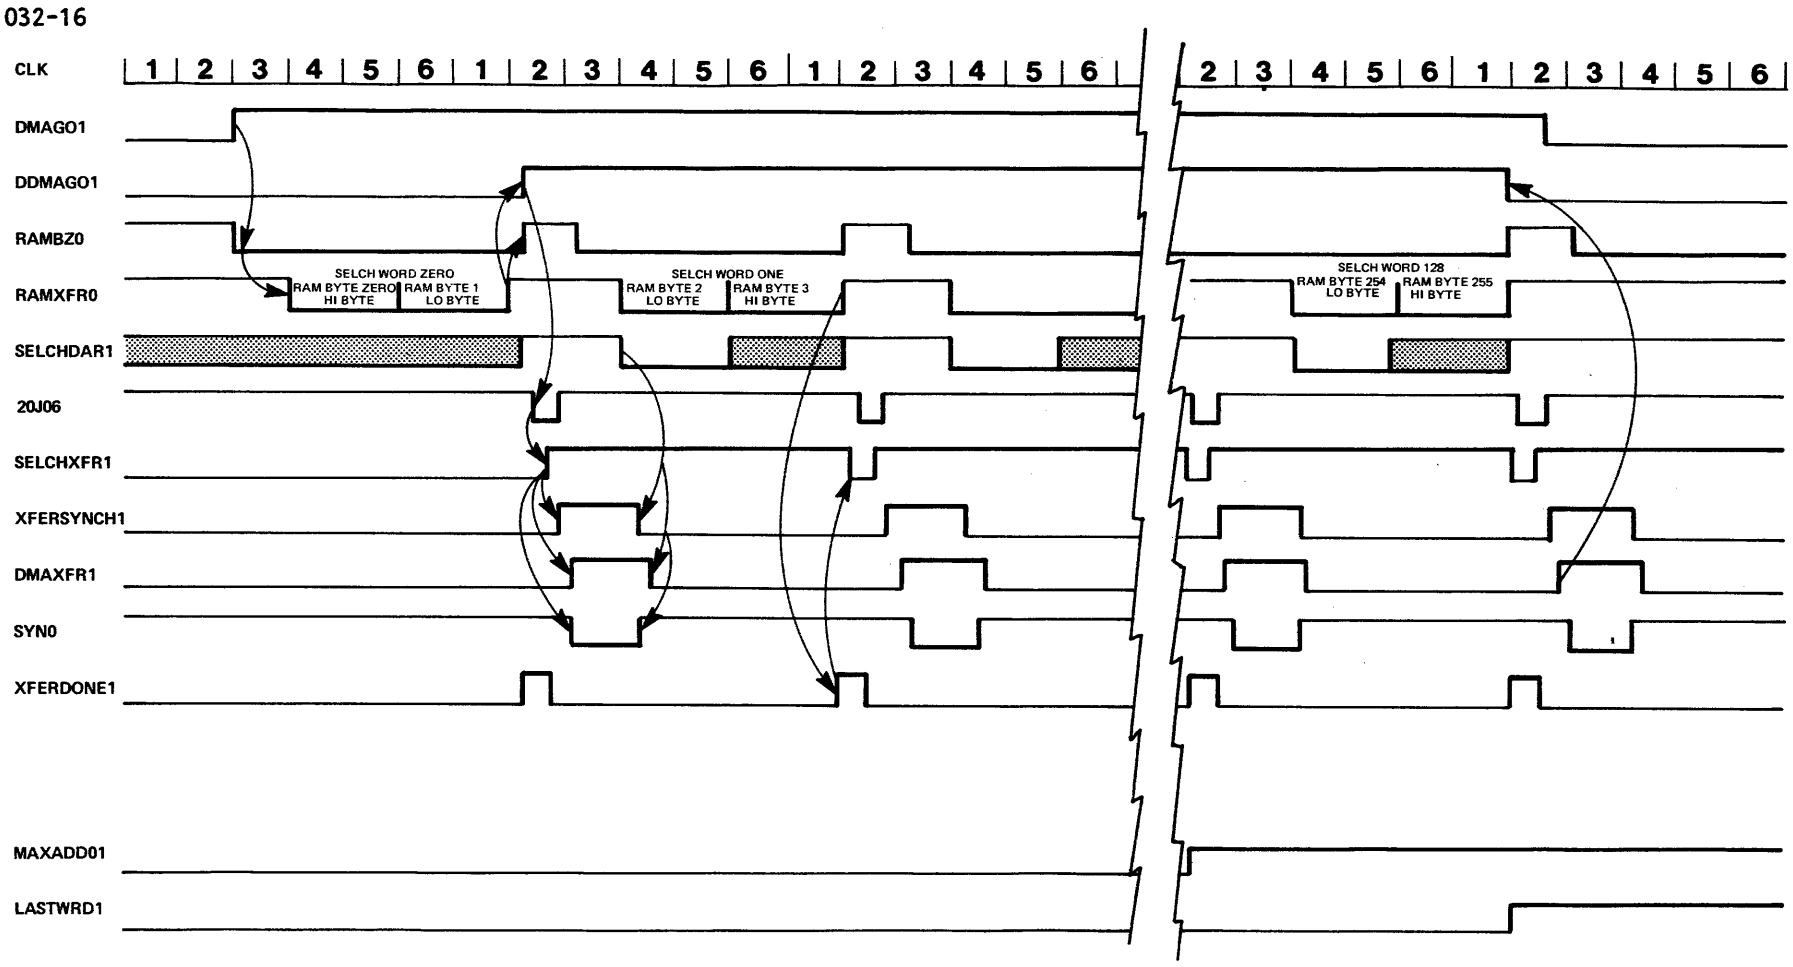

Figure 4-4 Timing Signals for a DMA Read Operation

Switching among RAM pages 1-3 during a DMA read operation is enabled with an active maximum sector count (MAXADD). MAXADD indicates that all 256 bytes of the current RAM page have been read. Once MAXADD is active, another RAMXFR operation occurs to transfer the last halfword from the current RAM page to the DMA registers. Then LASTWRD goes active, and a final DMAXFR occurs. Once this final halfword is transferred from the DMA registers, DMAGO resets. Additional pages read from the disk file are transferred in the identical manner as discussed above.

A DMA read operation ends normally by an active partial transfer (PARTIAL). PARTIAL indicates nonreception of a SELCH DR0 for 3 microseconds (μs). More specifically, if the IDC receives no DR0 from SELCH for 3 μs during a DMA read operation, PARTIAL is asserted. Its assertion indicates a termination of SELCH transfer.

4.3.2.2 Direct Memory Access (DMA) Write Operation

Steps 1-10 below present the sequence of operations occurring with a DMA write, i.e.; a write of a data sector to a disk file via IDC. Figure 4-5 shows the timing signals involved with a DMA write operation; see Appendix A for further description of the mnemonics.

1. IDC receives a write command (CMD0 function with associated data) from the processor.

2. IDC receives a SELCH DA0 function.

3. Microprocessor/sequencer microcode then asserts DMASTRT.

4. Step 3 sets DMAGO and resets LASTWRD. Activating DMAGO starts the DMA transfer from SELCH; i.e.; SELCHXFR, DMAXFR and XFRSYNCH go active.

5. Transfer sync (XFRSYNCH) clocks SELCH DMA data into the DMA registers.

6. A SYN is output to SELCH after successful completion of the SELCH DA function.

7. RAMXFR goes high: LDHIBYT loads the more significant byte of DMA data into the even RAM location; LDLOBYT loads the less significant byte of DMA data into the odd RAM location.

8. SELCHXFR remains asserted after the SYN output to prevent another DMA operation, just yet, for another SELCH DA0 reception. XFRSYNCH, DMAXFR and SYN go inactive.

9. XFRDONE activates, clearing SELCHXFR once both bytes are written into RAM.

10. DMA transfer repeats, starting from step 5, for each subsequently received SELCH DA0 function.

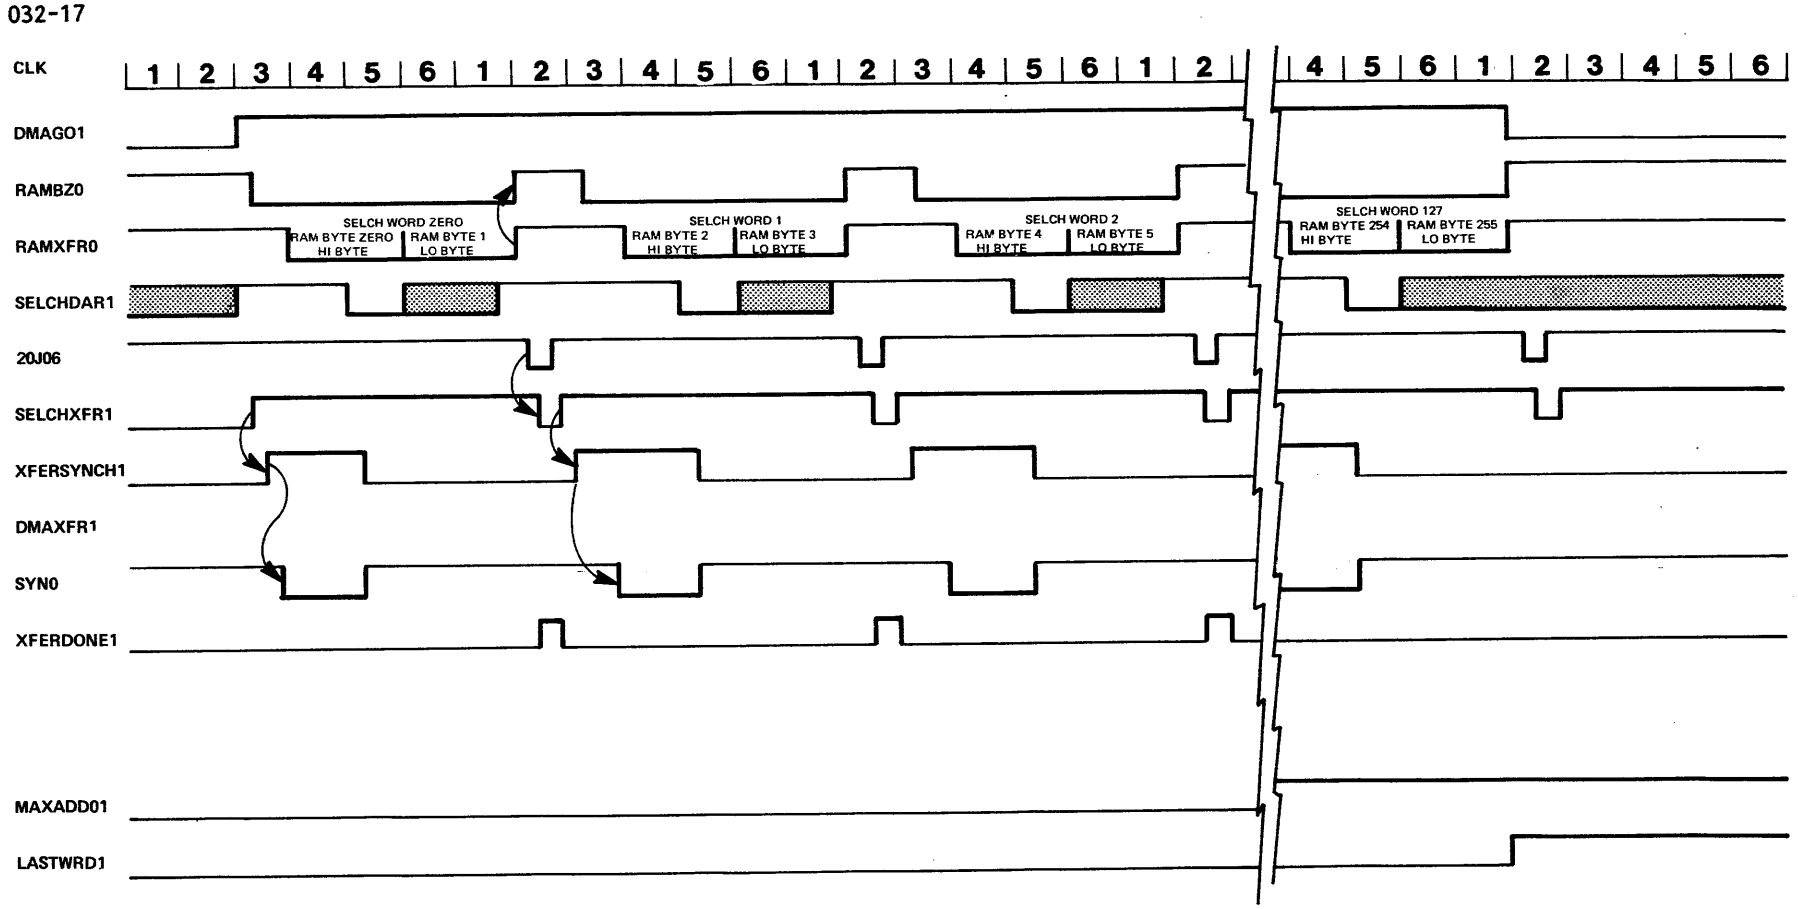

Figure 4-5 Timing Signals for a DMA Write Operation

Switching among RAM pages 1-3 during a DMA write operation is enabled with an active MAXADD, which indicates that 256 bytes have been written to the current RAM page. Once MAXADD is active, another RAMXFR operation occurs to transfer the last halfword from the DMA register to RAM. This final transfer activates LASTWRD to stop the DMA. LASTWRD gated with WRITE inactivates DMAGO. Additional pages read from the DMA registers are transferred in an identical manner.

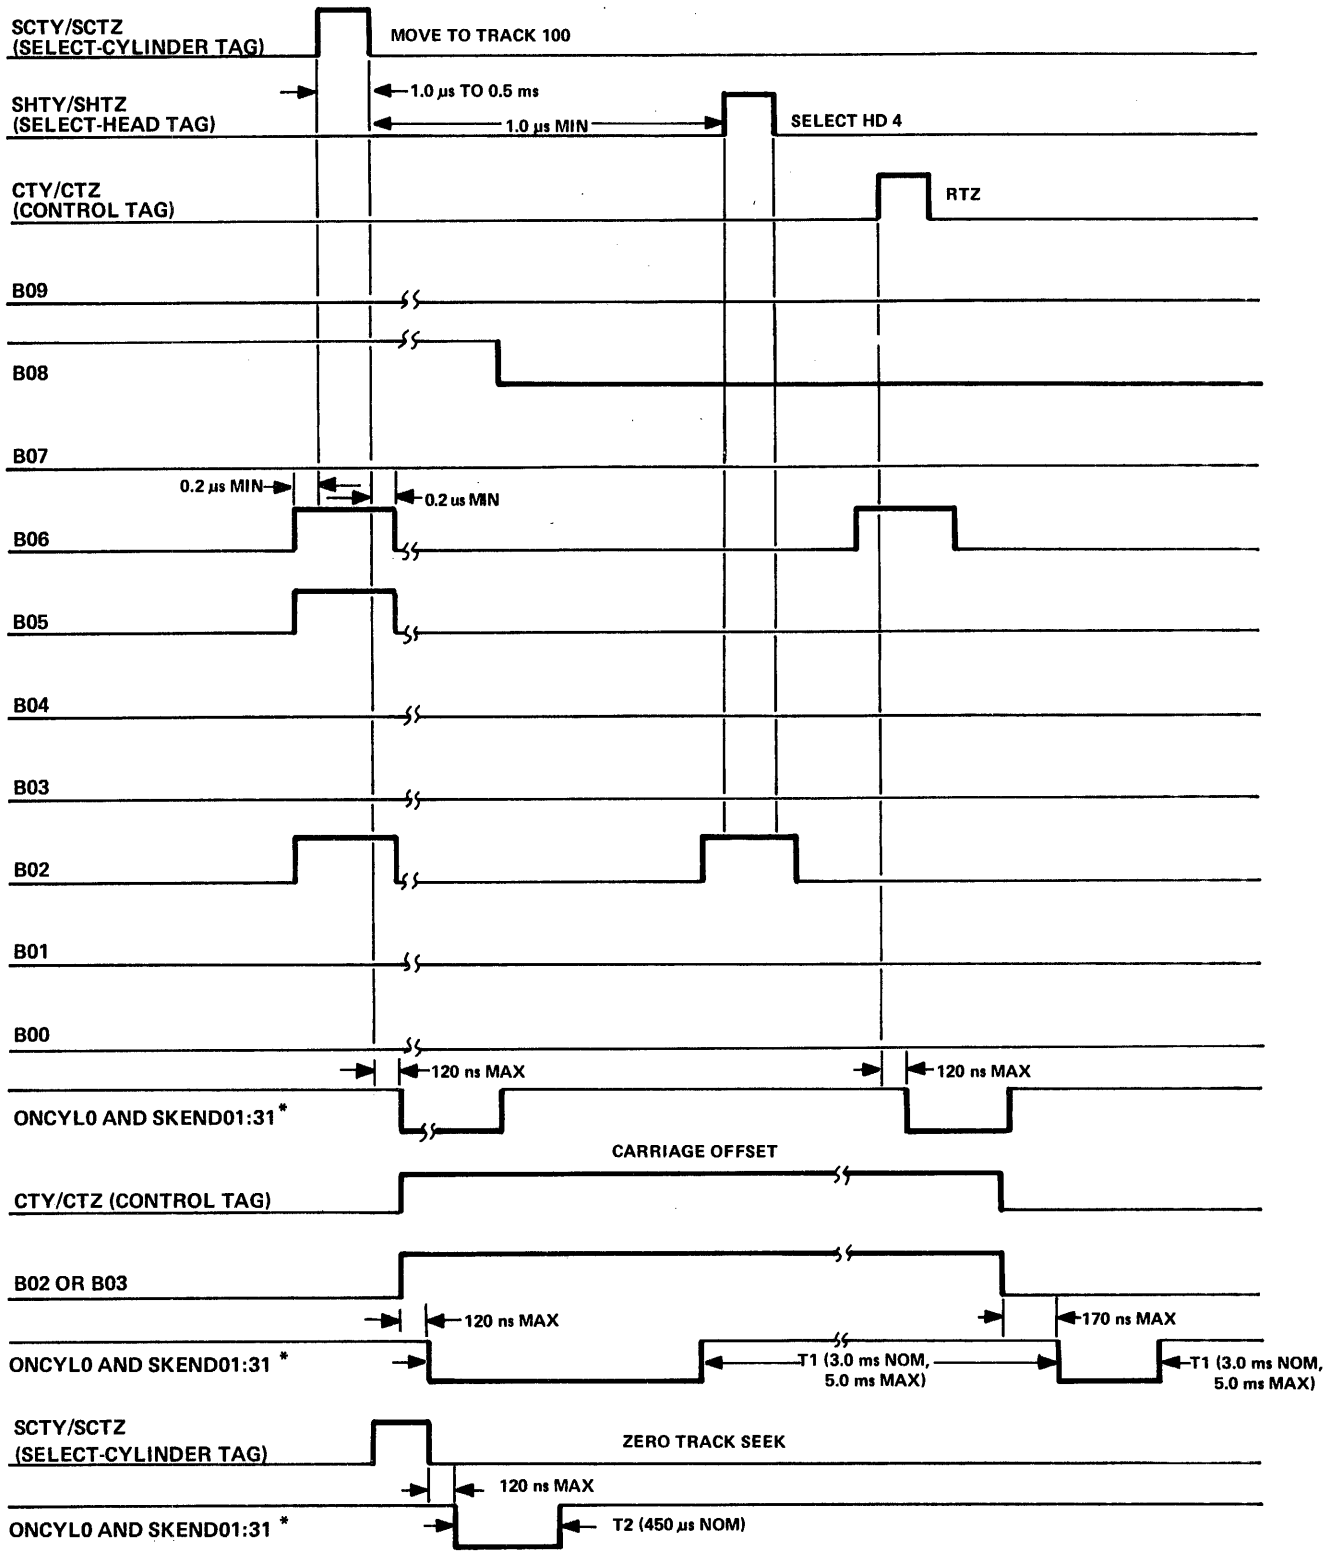
A DMA write operation ends normally by an active PARTIAL, which indicates nonreception of a SELCH DA0 for 3 μs. That is, if the IDC receives no DA0 from SELCH for 3 μs during a DMA write operation, PARTIAL is asserted. Its assertion indicates a termination of SELCH transfer.

4.4 DISK FILE INTERFACE

This portion of the IDC board intefaces disk files with the IDC controller logic. Specifically, it works with the microprocessor/sequencer logic to generate necessary control sequences, data and error correction code (ECC). Sections 4.4.1 through 4.4.6 discuss the major operational areas required for disk file I/O. Figure 4-6 presents timing signals for the various control and address lines discussed in these sections. For supplemental descriptions, see Appendix A.

4.4.1 Unit Selection

The first operation the interface must perform is disk file selection. To do this, the microcode places the unit select number (from RAM page 0) onto BD0:7. From BD0:7, the microcode-generated select pulse (SEL) loads the unit select number into the disk file number flip-flop (chip 23, sheet 17). The dual line driver (chip 18A, sheet 17) puts the disk file number onto the A-cable unit select lines (USEL0,USEL1). Next the microcode generates a unit select tag (USTAG). To do this, the microcode generates BDIO0:5 output specifying a load control tag (LDCT) function; see Table 4-2. To ensure proper disk file selection, the microcode issues a BDIO0:5 specifying an enable drive select (ESE) function. This ESE latches the unit selected tag (USEL0:3) and enables it as disk file selected (SEL0:3) onto BD0:7. Finally, the microcode compares SEL0:3 with the actual driver select bits 13 and 23 (DRV13,23) value. They should match to indicate proper selection.



*SIGNALS ARE IDENTICAL UNLESS SKER1 OCCURS.

Figure 4-6 Tag and Bus Timing

4.4.2 Selecting Disk File Cylinder and Head

The next operation in any read or write operation is to correctly position the disk file heads to the correct head and cylinder address. To position the heads, the microcode issues two BDIO0:5 outputs: the first specifies a load disk data bus (LDCB); the second specifies an LDCT. The LDCB loads the head address, latched in the load disk bus register (chip 15E, sheet 14), to BD0:7 and transmits it over the A-cable. The LDCT sends a select-head tag (SHT), latched in the load disk control tag register (chip 16E, sheet 15), to BD0:7 and transmits it over the A-cable.

Likewise, to select the particular cylinder, microcode issues a BDIO0:5 specifying an LDCB and another BDIO0:5 specifying an LDCT for the select cylinder tag (SCT). See Table 4-2. Since cylinder selection may take up to 65ms, the IDC goes idle once the SCT is issued. The IDC is then free to perform another command if the processor should issue one. While in the idle state, the ALU checks for a seek end (SKEND) from any disk file with the SHT in progress. To do this, the microcode issues a BDIO0:5 enable seek end (ESE) and loads SKEND onto BD0:7 via the selected seek-end register (chip 16C, sheet 15).

4.4.3 Disk File Status Check

When the processor requests a disk file status check, the IDC first ensures the particular disk file is currently selected. If that file is not selected, IDC selects it. The status of the disk file is latched by BDIO0:5 enable disk status (EDS) and put onto BD0:7 via the enable disk status register (chip 15C, sheet 14). The IDC then maps these status bits into the corresponding status bits for the Series-3200 Processor.

4.4.4 Decoding Index and Sector Pulses

During various read/write operations, the IDC must decode index (INX) and sector (SECT) pulses. INX pulses received from the B-cable are multiplexed into the disk drive index pulse (INDEX) via the selected index MUX (chip 12A, sheet 16), depending on the selected disk file. The SECT pulses from the B-cable are multiplexed into the Sector pulse (SECTOR) via the selected sector MUX (chip 12A, sheet 17), according to the selected drive. INDEX and SECTOR are output onto BD0:7 under microprogram control via the enabled disk status register (chip 15C, sheet 14) and disk status clear and enable (DCL).

4.4.5 Disk File Read Data Path

Once disk file heads are positioned over the data field of the sector to be read, microcode activates the read gate (RGATE). Then, read data (RDAT) and read clock (RCLK) from the selected disk file are received through the B-cable. Data read from the disk is selected by the 8-to-1 MUX (chip 9A, sheet 16), emerging as read/write clock (RWCLK).

SDATA is clocked into the serial-to-parallel converter (chips 14K and 15K, sheet 18) by RWCLK. When a sync word is detected here, SYNC goes active to enable the byte synchronizer (chip 22R, sheet 7) to generate data register ready (IPRDY). IPRDY indicates the serial-to-parallel converter contains two bytes of data to be written to IDC RAM. Microcode, which monitors IPRDY, then generates XFERHI and XFERLO to enable the less significant and more significant byte of read data to be transferred over BD0:7 to the IDC RAM. This halfword transfer occurs repeatedly until a full sector of 256 bytes are read. The same serial data is also fed to the ECC circuitry (sheet 11) as read serial disk Data (RSRO) for accumulation and comparison.

4.4.6 Disk File Write Data Path

When the heads are positioned over the data field of the sector to be written, microcode turns on the write gate (WGATE). At this time, the microcode will have filled the parallel-to-serial converter (chips 14J and 15J, sheet 18) with the first two bytes of RAM data to be written to the sector. To fill the parallel-to-serial converter with a halfword, microcode issues a BDIO0:5 transfer low byte (XFERLO) and transfer high byte (XFRHI). The less significant byte is loaded into the write shift register (chip 14F, sheet 18) from BD0:7. The more significant byte is loaded into the other half of the write shift register (chip 15F, sheet 18) from BD0:7.

The byte synchronizer (chip 22R, sheet 7) generates bit 151 inverted (09R08) to control the loading and shifting of the parallel-to-serial converter. When 09R08 is low and RWCLK jumps to high, data from chips 14F and 15F are loaded into the converter. When 09R08 is high and RWCLK jumps to high, data from the converter is serially shifted. Thus, the serial-to-parallel register is loaded by RWCLK and shifted for fifteen RWCLK periods.

Data emerges from the registers as write serial data (WSR) and goes to the data 8-to-1 MUX (chip 9A, sheet 16). The asserted WGATE signal causes this data to emerge as serial read data (SDATA). SDATA is fed into the shift register (chip 14K, sheet 18) and is shifted with RWCLK to produce RSRO. RSRO now goes to the data/ECC selector (gate 18R01, sheet 7), where it emerges as WDATA to be sent to the selected disk file over the B-cable. WDATA is also fed to the ECC Input (gate 16R04, sheet 11), where it is used to form the ECC.

The parallel-to-serial halfword transfer repeats until 256 bytes of data are written to the sector. Microcode then enables ECC feedback bit 31 (ECC31), the output of the ECC registers, onto the WDATA line. Consequently, the 32-bit ECC is appended to the sector of write data.

4.5 ERROR CORRECTION CODE (ECC) CIRCUITRY

This circuitry, although part of the IDC controller logic of Figure 3-6, is discussed here, after the disk file interface, because of its logical association.

The ECC circuitry shown on Sheet 11 of the IDC shematic, uses this formula to generate a 32-bit ECC:

$$X^{32} + X^{23} + X^{21} + X^{11} + X^{2} + 1$$

During a write operation, the ECC circuitry appends the generated ECC to the sector written to a selected disk file. During a read operation, the ECC circuitry compares the generated ECC with the ECC appended to the sector read from the selected disk. Whenever a mismatch occurs during this comparison, the ECC error detection bit (BITSR) becomes active (low).

The following operations occur for ECC generation during a disk file write:

1. The ECC registers (sheet 11) are initialized by a shift of 32 0-bits from the phase lock oscillator (PLO) field of the formatted disk media.

2. Microcode sets the accumulate ECC (ACCECC) signal.

3. Serial data (RSRO) to be written to a disk sector is fed through the ECC registers. The first 1-bit input sets ECC contents according to the above generation formula; i.e.; the first 1-bit sets the 32nd, 23rd, 21st, 11th and 2nd flip-flops.

4. Each additional bit causes mixing, or accumulation.

5. Once the ECC registers accumulate the last bit of the sector to be written, microcode asserts ECC Off (OFF) to place the registers into the shift mode. Consequently, the ECC is appended to the written sector.

The following operations occur for ECC generation/comparison during a disk file read:

1. The ECC registers (sheet 11) are initialized by a shift of 32 0-bits from the PLO field of the formatted disk media.

2. Microcode sets the accumulate ECC (ACCECC) signal.

3. Serial data (RSRO) read from a disk sector is fed through the ECC registers. ECC accumulation begins with the first 1-bit after the sector sync word. This bit sets ECC contents according to the above generation formula.

4. Each additional bit causes mixing, or accumulation.

5. Once the ECC register accumulates the last bit of the read sector, the ECC appended to that sector is compared to the newly accumulated ECC. The comparison is accomplished by shifting the 32-bit ECC into the ECC registers.

6. If the two ECCs match, BITSR remains inactive (high) and the ECC registers contain only zeros. The current sector, just loaded into IDC RAM, is enabled for DMA transfer.

7. If the two ECCs mismatch, indicating an ECC error, BITSR goes active (low) and the ECC register contents are nonzero.

8. Microcode automatically rereads the same sector. If the error persists, microcode implements ECC operation as discussed below.

9. To internally correct an ECC error of 11 bits or less, the microcode:

    a. Generates BDIO0:5 load ECC low (ECCLO), which results in ECC21:23 being read onto BD5:7 of the BD0:7 bus. (See Table 4-2, BDIO0:5 value X'02'.) These three syndrome bits, needed to perform the correction, are stored in RAM.

    b. Generates BDIO0:5 load ECC high (ECCHI), which results in ECC24:31 being read on to BD0:7. (See Table 4-2, BDIO0:5 value X'03'.) These eight syndrome bits, needed to perform the correction, are also stored in RAM.

    c. Shifts the ECC register, still containing the syndrome bits, 40,907 times to initialize it to the first bit position of the read sector, which is now in the current RAM page.

    d. Shifts the ECC register one bit at a time up to 2,048 bit shifts. After each shift, microcode examines BITSR for a low (error) setting:

If BITSR is low, the microcode ORs the ECC21:31 syndrome bits with eleven bits in RAM, starting at the same bit position. This operation implements the correction. Execution now repeats from step (5).

If BITSR is not found as low throughout the 2,048 shifts, an additional 32 bit shifts are examined to see if the error occured in the 32-bit ECC itself. If BITSR equals low here, the error occurred in the ECC, thus the data was read correctly; execution repeats from step 5. However, if BITSR is still not found as low, an uncorrectable ECC error exists. The IDC controller status will be set to X'0B'. See the IDC Programming Manual for further description of this status.

TABLE 4-5. MICROINSTRUCTION BITS I3:5 FOR ALU FUNCTIONS

I3:5 VALUE			OCTAL CODE	ALU FUNCTION*	FUNCTION MNEMONIC
I5	I4	I3			
0	0	0	0	R+S (R plus S)	ADD
0	0	1	1	S-R (S minus R)	SUBR
0	1	0	2	R-S (R minus S)	SUBS
0	1	1	3	R OR S	OR
1	0	0	4	R AND S	AND
1	0	1	5	R AND S (not R and S)	NRS
1	1	0	6	R XOR S (R exclusive or S)	XOR
1	1	1	7	R XOR S (R exclusive nor S)	XNOR

* R and S respectively refer to the two input ports, R-MUX and S-MUX, represented in Figure 4-1. Refer to Table 4-6 for I3:5 combinations with the I0:2 bits.

3. ALU Destination Selection with I6:8

I6:8 bits select the destination of the F0:3 output resulting from ALU execution of bits I0:5. As illustrated in Figure 4-1, ALU output goes to one or more destinations: the MicroRAM circuitry, the Q-register circuitry and the Y-output MUX. And depending on the value of I6:8, this output can be up- or down-shifted. Table 4-7 shows the destination control associated with I6:8. With any value of I6:8, and with an active (low) POE input, the Y-output MUX outputs the F0:3 results over the microprocessor bus BD0:7.

APPENDIX A

TABLE OF IDC MNEMONICS

The following pages contain the mnemonics found in the intelligent disk controller (IDC) schematics of Appendix B and discussed throughout Chapters 1 through 4 of this manual. The SOURCE column in this table specifies the sheet number and grid coordinates of the location for each mnemonic.

MNEMONIC	SOURCE	NAME	COMMENT
ACCECC1	7C4	Accumulate ECC	Allows ECC generation.
ADRS01	3B8	IDC or Disk File Address	Input from the processor to select a device (IDC or disk file) for an I/O operation. Data bits D080:150 contain this address.
ADRS1	3D8	Received ADRS0	Indicates an active ADRS0 signal.
ADRSYN0	3N9	Address Sync	A sync return for address selection.
AE/OE1	8L4	RAM Address Enable	Gates the address lines to the RAM. That is, it selects the RAM address source: a high selects RAM0:7 from the pipeline register, or a low selects RAM0:7 from the RAM address counter.
ANYCRY1	13M1	Carry into ALU	The carry generated from the previous ALU cycle or the microcode.
AR01:31	9H2	ALU A-Register Selection Bits 0-3	A01:31 before the pipeline register.
ASERVO00:30	17D5	Disk Drive Write Clocks 0-3	Output to disk files.
ATN01	3M3	Attention	Output to the processor to signal an interrupt pending.
A01:31	9M2	A-Register Address Bits 0-3	A 4-bit binary value for selecting one of the ALU registers as the source A-register.
BAOE1	13C9	Inverted RAM Address Enable	AE/OE1 inverted.
BD01:71	12C6	8-Bit Microprocessor Data Bus	The main data path among the functional blocks of the IDC. It buses various data and control bytes.
BDIO01:51	8M9	Bus Data I/O and Control Bits 0-5	A 6-bit code that controls the source and destination for BD0:7 and provides numerous control signals. See Table 4-2 for detailed description.
BITON0	6B1	Masked CC Bit	Masked condition-code bit of the disk file status.
BIT151	7F3	Carry Bit 15	Carry bit from the serial-to-parallel converter for synchronizing microprocessor data with serial disk data.

MNEMONIC	SOURCE	NAME	COMMENT
BITSR01	11L2	ECC Error Detection Bit	A zero indicates a data read error.
BL	6K8	Reset SELCH Transfer	Terminates DMA transfer to/from SELCH.
BRA01:91	10L6	Branch Address Bits 0-9	A 10-bit branch address to the microprogram sequencer. When output from the pipeline register, BRA0:9 specify the location of the next microinstruction to branch to. BRA0:9 also load the microprogram sequencer with a count value for loop iteration. When output from the map PROM, BRA0:7 provide constant data or a branch address for a map jump.
BUSAOE0	13D9	LDR Counter RAM Address	Selects the LDR counter as the RAM address.
BUSSW0	6G3	Bus Switch	Output to SELCH to indicate IDC support for the new high-speed SELCH protocol, with an I/O Bus Switch. Pins W1 and W3 on the IDC board should be strapped for this support.
BUSYA1,B1	14A6	Differential Dual-Port Busy	Informs this IDC that a disk file has been acquired by another IDC. (Applicable only to dual-port operation.)
BUSY1	14D6	Busy Signal	Received from disk file.
B00Y1,B00Z1 thru B10Y1,B10Z1	14M-, 15M-	Differential Data Bus Bits 0-10	Output to disk files for control and address data. B10Y1,B10Z1 is a spare. These lines are alternately referred to as B00:10. See Tables 3-1 and 3-2 for further description.
B01:31	9M5	B-Register Address Bits 0-3	A 4-bit binary value for selecting one of the ALU registers as the source/destination B-register.
CARRY31	12C3	Carry Bit 3	Carry-out associated with the last operation of the less significant ALU slice.
CARRY71	12E3	Carry Bit 7	Carry-out associated with the last operation of the more significant ALU slice.
CA081:151	3C2-	Controller Address Bits 8-15	IDC address (of this controller) to be sent as MD08:15 input to the data transceivers or to the processor along with the SYN0 signal.

MNEMONIC	SOURCE	NAME	COMMENT
CBIT0	14J2	Data Bit 0	With CTAG3, it indicates an ongoing write operation to a disk file, i.e.; when both CTAG3 and CBIT are high, a write is in progress.
CBIT1	14J2	Data Bit 1	With CTAG3, it indicates an ongoing read operation to disk file, i.e.; when both CTAG3 and CBIT are high, a read is in progress.
CCLK0	19D3	Gated 10MHz Clock	Used to generate timing signals within the IDC.
CCMUXP1	6D2	CC MUX Output	The multiplexed condition code resulting from the disk file status.
CC0	12H1	Condition Code	Indicates a pass or fail for one of eight conditions. The microprogram sequencer uses CC for a next address calculation, like a conditional branch or return. See MA:MC.
CENB0	12L8	RAM Chip Enable	Enables RAM output onto BD0:7.
CINTCLR0	10J3	Internal Clear	Resets SECTOV, the watchdog timer, and various statuses of the IDC.
CINT1	4L6	Controller Interrupt	Indicates the controller portion of the IDC is generating an interrupt to the processor.
CIN1	9M9	Carry-In	Microcode-generated carry input to the ALU.
CLK10:60	19J2	Clock Phases 1-6	One of six 62.5ns phases of the 375ns IDC cycle.
CLK12D0	19K3	Delayed Clock Phase 1/2	Delayed summation of CLK10 and CLK20.
CLK12345D1	19G1	Delayed Clock Phase 1-5	The clock phase feedback to the input stage of the clock generator to regenerate the other clock signals.
CLK150,151	19M2	Clock Phase 1/5	Summation of CLK10 and CLK50.
CLK230,231	19M3	Clock Phase 2/3	Summation of CLK20 and CLK30.
CLK34D0	19K3	Delayed Clock Phase 3/4	Delayed summation of CLK30 and CLK40.
CLK450,451	19M3	Clock Phase 4/5	Summation of CLK40 and CLK50.

MNEMONIC	SOURCE	NAME	COMMENT
CLK641	19K2	Clock Phase 6/4	Summation of CLK60 and CLK40.
CLOC0	3L6	Controller Latched Output Command	Indicates a received CMD0 signal from the processor, e.g.; read, write or format sector.
CL0701	3B9	Early Power Failure	Input from the processor to signal an imminent power failure.
CMD01	3J4	Command	Input from the processor to signal the presence of a command on data bits D080:150.
CNT1	8L6	RAM Page Counter Enable	When high, it enables the RAM page counter to increment to the next page.
=CONT	3E6	Equals Controller	Indicates that the received controller address matches the address of this IDC. Also, it indicates that the FUNC0:2 bits apply to this selected IDC.
CONTACK0	4N5	Controller Acknowledge	An acknowledgment from the processor for the controller address of this IDC.
CONTSEL1	3H6	Controller Selected	Indicates the processor has selected the controller address of this IDC.
CONTSYNC0	3E8	Controller Sync Return	Indicates the IDC has properly accepted and responded to a control line signal.
CON0	5M5	Microcode Clear to Zero	Internally resets the IDC and causes the microcode to go to zero.
CRST0	19F7	Controller Reset	Either an EXTCLR or an OCRST.
CTAG31	15J8	Control Tag 3	Causes execution of the disk file function associated with the contents of B00:B09. See Table 3-1.
CTLOPTCL1	3F5	Controller in Optional Protocol	See OPTPTCL1.
CTY1,Z1	15M-	Differential Control Tag	Output to disk files to indicate that bus lines B00:09 are supplying a driver command.

MNEMONIC	SOURCE	NAME	COMMENT
DAR1	7H7	Data Available or Requested	Indicates a DA0 or a DR0 received from the SELCH during a DMA.
DATA001:071	5G2-	Data Bits 0-7	More significant byte of DMA data to be sent to SELCH.
DATA081:151	5G5-	Data Bits 8-15	Less significant byte of DMA data to be sent to SELCH.
DA01	3J2	Data Available	Input from processor or SELCH to inform the IDC of a write operation to the selected IDC or disk file. Data is available on data bits D000:150.
DA1	3K2	DA0 Received	Output resulting from a DA0 input.
DCL0	5M7	Disk Status Clear and Enable	Clears various counters and registers associated with the disk file interface.
DDMAGO0,1	6C7	Delayed DMA Go	A delayed DMAGO signal -- a one-buffer delay on a read operation.
DE0	5K3	Data Enable	Reads the map PROM register to BD0:7.
DLYSUS1	6L9	Delay 3 Microseconds	Sets partial flip-flop if SELCHDAR1 is not received within 3μs and if the partial counter is not enabled.
DLYSYNC0	6M2	Delayed Sync Return	Either the DMA sync signal to the SELCH (resulting from SELCHSYN) or the interrupt-acknowledgment signal (resulting from OURACK0) to the processor.
DMAGO0,1	6J6	DMA Go	Indicates that the IDC is performing a DMA transfer to the SELCH.
DMASR0	6H1	DMA Status Request	A status request from the SELCH to this idle IDC.
DMASTRT0	5M5	DMA Start	Microcode bit to start DMA operation. It sets the DMAGO flip-flop and resets the LASTWRD flip-flop.
DMAXFR1	6S5	DMA Transfer	Indicates an ongoing DMA transfer.
DMA130,230	12K8	DMA Bits 13 and 23	DMA RAM-page bits, encoded.

MNEMONIC	SOURCE	NAME	COMMENT
DRV131:231	17K4	Drive Select Bits 13 and 23	Two binary bits to select one of four disk files.
DR01	3J2	Data Request	Input from procesor or SELCH to inform the IDC of a read operation from the selected IDC or disk file. Data is requested from D000:150.
DR1	3K1	DR0 Received	Output resulting from DR0 input.
DSBCRY0	13J1	Disable Carry	Clears CARRY7.
D000:150	4E-	Data Bits 0-15	I/O consisting of data, an address, a command or a status.
D001:151	4E-	Received-Data Bits 0-15	Output corresponding to D000:150 for received data from the SELCH/MUX bus.
EBLD01:41	5J7	Enable-Decoder Bits 0-4	Select one of the five BDIO decoders (the 3-8 decoders).
EBLOUT0	4G3	Enable MUX Output	Enables MUX bus data output, i.e.; sets the transceiver mode to transmit or receive.
EBLPRTL1	6H9	Enable Partial	Enables the partial counter to determine if a partial DMA has occurred.
EBLTCLK0	14D9	Enable Clock	Can be used in an IDC developmental system to disable the 16MHz clock and to enable TSTCLK.
ECCCLK1	7M3	ECC Clock	Clock to ECC circuitry for generating correction code.
ECCHI0	5K3	Load ECC High	Indicates the more significant byte of the ECC syndrome is loaded onto BD0:7. Specifically, it reads ECC24:31 to BD0:7.
ECCLO0	5K3	Load ECC Low	Indicates the less significant byte of the ECC syndrome is loaded onto BD0:7. Specifically, it reads ECC21:23 to BD5:7.
ECC001:311	11-	ECC Output Bits 0-21	The 32 bits of the ECC generator.
ECC311	11A6	ECC Feedback Bit 31	The 32nd bit of ECC fed back into ECC circuitry.

MNEMONIC	SOURCE	NAME	COMMENT
EDS0	5K5	Enable Disk Status	Indicates that the disk file status register is loaded onto BD0:7.
EOXFR1	6R4	End of Transfer	Inverted PARTIAL0 input.
ESE0	5K5	Enable Seek End and Drive Select	Indicates that the seek-end/drive-select register is loaded onto BD0:7.
ESTBRA0	5K6	Establish Branch Address	Enables disk status into the condition code MUX.
EXTCLK1	19C4	External Clock	A test clock signal associated with TSTCLK0.
EXTCLR0	3H7	External Clear	An externally generated IDC reset resulting from the ORing of three signals: TESTCLR0, SCLR0 and CL070.
FAULTA1,B1	14A1	Differential Fault	Input indicating a fault condition at a disk file.
FAULT1	14D2	Disk Drive Fault	Indicates that the selected disk file is experiencing a fault condition.
FA081:151	3G1	File Address Bits 8-15	File address to be sent as MD081:151 input to the Data Transceivers, or to be sent to the processor along with the sync signal SYN0.
FILEACK0	4N6	File Address Acknowledge	An acknowledgment from the processor for one of the disk file addresses of this IDC.
FILESEL1	3J7	File Selected	Indicates the processor has selected one of the disk file addresses of this IDC.
FILESYNC0	3L9	File Sync Return	Indicates that an attached disk file has properly accepted and responded to a control line signal.
=FILE1	3F6	Equals File	Indicates that the received file address matches the address of a disk file at the IDC. It also indicates that the FUNC0:2 bits apply to a selected disk file.
FILE130,131 and FILE230,231	3H8-	File Address Bits 13 and 23	Two binary bits with one of the four disk file addresses (0-3).

MNEMONIC	SOURCE	NAME	COMMENT
FINT1	4L6	File Interrupt	Indicates a disk file is generating an interrupt to the processor.
FLDA0	3L7	File Data Available	Indicates a disk file received a DA0 signal from the processor. The data available is the cylinder or head address of the currently selected disk file.
FLDR0	3L7	File Data Request	Indicates a disk file received a DR0 signal from the processor. Consequently, the disk file returns an RPS or an X'FE' to the processor.
FLOC0	3L8	File Output Command	Indicates a disk file received a CMD0 signal from the processor, e.g.; seek, set head or RTZ.
FLSR0	3L7	File Status Request	Indicates a disk file received an SR0 signal from the processor. As a result, the IDC returns the status of the currently selected disk file.
FMTENBL1	3G6	Format Enabled	Indicates that toggle 8 of the file 0 Address Switch is pushed down to the 1-position to enable IDC formatting.
FOUND0	5M8	Sector Found	Test point to indicate whether or not the IDC has found the sector to be written to or read from.
FUNC00:20	3N6	IDC Function Lines 0-2	One of eight encoded functions output to BD0:7. See Table 4-9.
F=0	12F2	Function Equals Zero	Indicates ALU computation equals zero.
GME0	12K1	Gated Map PROM Enable	Enables the map PROM outputs onto BRA0:7.
GOTO00	19M6	Go to Address Zero	Forces microcode to address zero.
GPD081:151	5F9	General-Purpose Data Bits 8-15	Control data to be sent as MD081:151 input to the data transceivers.
HOLD0/PICK0	17K2	Power Sequence Hold/Pick	Two lines with which the processor picks and holds the power sequencing capability for disk files in the remote mode. When the processor is turned on, IDC logic applies a ground to these lines to sequentially power-up the attached disk files.

MNEMONIC	SOURCE	NAME	COMMENT
HW0	6F2	Halfword Mode	Output to SELCH indicating that this IDC is a halfword-oriented device.
IDLE0,1	6D9	Controller Idle	Indicates IDC not performing any operation.
ILDA0	3L5	Idle Controller Data Available	Indicates a received DA0 signal from the processor while the IDC was idle. Specifically, it indicates the processor has data (sector number) to be written to the IDC.
ILDR0	3L5	Idle Controller Data Request	Indicates a received DR0 signal from the processor while the IDC was idle. Serves no function; just results in zero being returned to the processor.
ILSR0	3L6	Idle Controller Status Request	Indicates a received SR0 signal from the processor while the IDC was idle. It directs the IDC to return the current IDC status to the processor.
INDEX1	16M2	Disk-Drive Index Pulse	Indicates that the index pulse is being received from the selected disk file.
INGPG1	13C8	Enable Page Counter Increment	Enables the page counter to be incremented while sectors are read from a disk file.
INTCLK1	19C3	Internal Clock	A 16MHz signal associated with OSC0.
INTCLR0	10M3	Internal Clear	Internally generated IDC reset signal.
INTDATA0	5M5	Interrupt Data	Loads interrupt register with data.
INTREQ1	4K3	Interrupt Request	Indicates that this IDC is requesting an interrupt from the processor.
INX0A1,0B1 thru INX3A1,3B1	16H1-	Differential Index	Input from a disk file to mark the leading edge of sector zero for every disk revolution.
IpRDY1	7F4	Data Register Ready	For a read it indicates the serial-to-parallel converter contains the two bytes of data written to the IDC RAM. For write, it indicates the parallel-to-serial converter is empty.

MNEMONIC	SOURCE	NAME	COMMENT
IPRY0,1	3M4	Input Ready	Indicates the write shift register (WSR) is filled or that the read shift register (RSR) is emptied.
I01:81	9N6	ALU Instruction Bits 0-8	The nine instruction bits required by the ALU to perform an operation. See Tables 4-4 thru 4-7 for further description.
LASTDA0	6J5	Last Data Available	Indicates the last DA0 signal received from SELCH during a DMA transfer.
LASTWRD1	6K7	DMA Last Halfword	Indicates the last halfword of a sector is being DMAed via SELCH.
LBD01:71	12K1	Latched Bus Data Bits 0-7	Latched data from BD0:7 for ALU input. Or, as input to the map PROM, LBD01:71 causes output of either constant data or a microroutine address.
LDA1	3N2	Latched Data Available	Latch signal corresponding to DA input.
LDCB0	5N3	Load Disk Data Bus	Loads disk Data Bus Bits, B00:07. See Table 4-2.
LDCT0	5N3	Load Disk Control Tag	Loads control tags and B08:09. See Table 4-2.
LDDMA0,1	5N3	Load DMA	Loads RAM page and mode (read or write) into DMA.
LDDSK0	5N3	Load Disk	Loads the bus RAM-address counter for disk I/O.
LDHIBYT1/ LDLOBYT1	6C6	Load High/Low Byte	Loads the halfword data registers for MUX bus I/O from BD0:7.
LDPAGE0	5N3	Load RAM Page Number	Causes the RAM page number to be loaded from BD0:7.
LDR1	3M1	Latched Data Request	Latch signal correspponding to DR input.
LME1	12L4	Latched ME0	Latch signal corresponding to ME0.
LOC1	3N3	Latched Output Command	Latch signal corresponding to the OC input.
LOf0	5N5	Clear Diagnostic	Causes the diagnostic flip-flop to reset and the error LED to go off.

MNEMONIC	SOURCE	NAME	COMMENT
LON0	5N4	Turn On Diagnostic	Causes the diagnostic flip-flop to set and the error LED to light.
LP131:231	12H8	Page Counter Bits	Binary value to identify RAM pages 1-3 of the disk file during a read. (Page 0 is reserved for constants, statuses, etc.)
LSR	3N2	Latched Status Request	Latch signal corresponding to the SR1 input.
MAXADD01	6H8	Maximum Sector Count	Indicates that 256 bytes of data have been DMAed via the SELCH.
MAXADD11	13D2	Maximum Address Counter 1	Indicates that the maximum DMA count is reached with the less significant DMA counter.
MAXADD21	13D4	Maximum Address Counter 2	Indicates that the maximum DMA count is reached with the more significant DMA counter.
MA1:MC1	8M7	Condition Code MUX Selection Bits A-C	Three bits to select one of eight condition codes for the next address calculation. See Table 4-3.
MCE1	8L5	RAM Chip Enable	Enables the RAM for a read or write operation.
MD081:151	4C-	Multiplexed Data Bits	One of four multiplexed data sources to be sent to the SELCH or processor.
MEC0	5M7	Enable ECC Shift	Enables the ECC register to shift continually.
ME0	5M8	Map PROM Enable	Reads the map PROM location to BRA0:7 and to the map register.
MI1	9M9	CC MUX Inverter Bit	Fourth bit of the COND MUX CTL line; see Figure 3-6. If MI is not set, condition code (CC) output is inverted.
MOUT1	12G1	Condition Code MUX Output	Output consisting of one of the eight condition code inputs.

MNEMONIC	SOURCE	NAME	COMMENT
MUX131,231	4H2	MUX Control Bits 13 and 23	Two binary bits for selecting one of four registers to be output to the MUX bus: general-purpose data register, file address register, controller address register or DMA data register.
MWE1	8L5	RAM Write Enable	Enables RAM to be written to.
NEWFILE1	3M8	New File	Indicates a new disk file has been addressed by by the processor.
NOP0	5K2	No Operation	(Not connected or used.)
NOWRDS0	6M5	No Words	Indicates no words have yet been transferred in this DMA sequence.
NXCIN1	13L1	Latched ALU Carry Bit	CARRY71 latched.
OBCADY1,Z1	17K3	Differential Open Cable Detect	Output to disk files to indicate an open A-cable or a loss of IDC power.
OCRST0	4L9	Output Command Reset	A reset command from the processor to the IDC.
OC1	3K4	CMD0 Received	Output resulting from CMD0 input.
OFF0	5N7	ECC Off	Terminates ECC generation on read. On write, it causes ECC to be written.
OFLOW1	12E2	Overflow	Indicates the ALU operation produced an overflow.
ONCYLA1,B1	14A3	Differential On-Cylinder Detection	Input status from a disk file to indicate positioned heads.
ONCYL0	14D3	Not On Cylinder	Indicates the disk drive head is not on cylinder.
ON0	5N7	ECC On	Starts ECC generation on read. On write, it causes WSR data to be written
OPTPTCL1	3F6	Optional Protocol	Indicates that toggle 7 of the file 0 address Switch is pushed down to the 1-position to employ the new high-speed SELCH protocol.

MNEMONIC	SOURCE	NAME	COMMENT
OSC0	19B3	Oscillator	The 16-MHz oscillator of the IDC.
OURACK0	4M4	Our RACK0	Indicates a received RACK0 is for this IDC, which has an interrupt pending.
OVERRUN0,1	6M6	Data Overrun	Indicates a data overrun during a DMA operation with SELCH.
PAD1	4J9	Program Controller Reset	Indicates that the processor has sent an OCRST to the IDC.
PAGE131:231	12M8	RAM Page Address Bits 13 and 23	Two bits to select one of three RAM pages (1, 2 or 3) for either DMA or disk file I/O.
PARTIAL0	6M7	Partial Transfer	A partial sector transfer occurred.
PA0SPA90	10K2	SPA91 Inverted	See comment for SPA91.
PA01:81	10A1	PROM Address Bits 0-8	The nine least significant bits of the PROM address.
PA90,91	10M2	PROM Bank Address Bit 9	PA90 selects the second PROM bank of 512 words. PA91 selects the first PROM bank of 512 words.
PICK0	17K1	Power Sequence Pick	See HOLD0/PICK0 in this table.
POE0,1	9M9	ALU Output Enable	Indicates that the ALU output goes to BD0:7.
PROMEN1	10J1	PROM Enable	When low it enables access to the PROM banks.
PZ0	8L4	RAM Page Zero	Indicates selection of RAM page 0.
P11:31	Global	Pull-Up Resistor	5-volt pull-ups for guaranteed highs as inputs to to IDC logic.
QSHFT21	12A2	Right-Shift of Q-Register	Right-shifts the contents of the Q-register (a barrel shifter) of the ALU.
RACK01	4J6	Receive Acknowledgment	Input from the processor to signal an interrupt acknowledgment.
RAE/OE1	8C5	PROM's RAM Enable or Output Enable	AE/OE1 before it enters the pipeline register.

MNEMONIC	SOURCE	NAME	COMMENT
RAMBZ0	7G9	RAM Busy	Indicates the RAM is busy with a read or write.
RAMXFER0,1	7G7	RAM Transfer	Indicates the IDC is performing a data transfer to the RAM.
RAM01:71	8M1	RAM Address Lines 0-7	Eight bits that select one of 256 RAM locations in a page.
RBC0	5K5	Read Bus Control	Various IDC statuses gated onto BD0:7.
RBDIO01:51	8C5-	PROM's BDIO Bits 0-5	Bus data I/O and controls before the pipeline register.
RBD0	5K5	Read Bus Data	Indicates DATA08:15 are gated onto BD0:7.
RBRA01:91	8H7, 10D6-	PROM's Branch Address Bits 0-9	BRA01:91 before they enter the pipeline register.
RBS0	5K6	Read Bus Status	Reads bus status to BD0:7.
RB01:31	9D4	PROM's ALU B-Register Selection Bits 0-3	B01:31 before they enter the pipeline register.
RCLK0A1,0B1 thru RCLK3A1,3B1	16A6-	Differential Read Clock	Input from a disk file to synchronize data read from it.
RCLK01:31	16D5-	Read Clock	Read clocks from a disk file to IDC.
RCNT1	8H6	PROM's RAM Page Counter Enable	CNT1 before it enters the pipeline register.
RCN1	9D8	PROM's Carry Bit	CIN1 before it enters the pipeline register.
RDATA01:31	16D1-	Read Data	Data read from a disk file to the IDC.
RDAT0A1,0B1 thru RDAT3A1,3B1	16A1-	Differential Read Data	Input data read from the disk file.
RDHIBYT0, RDLOBYT0	6D5-	Read High, Low Byte	Reads the high- or low-order data byte to BD0:7.
READY0	14D4	Selected Disk File Ready	Indicates the selected disk file is ready for I/O.

MNEMONIC	SOURCE	NAME	COMMENT
READ1	12D8	IDC Read	Indicates the IDC is currently executing a read operation.
REGSYN0	6J4	Register Sync	Indicates that the IDC received one of the four control functions SR0, CMD0, DR0 or DA0.
RGATE0, RGATE1	18J9, 16D9	Read Gate	Read Gate of the selected disk file.
RI01:81	9D4	PROM's ALU Instruction Bits 0-8	I01:81 before they enter the pipeline register.
RMA1:RMC1	8H8	PROM's Condition Code MUX Selection Bits	MA1:MC1 before they enter the pipeline register.
RMCE1	8C5	PROM's RAM Chip Enable	MCE1 before it enters the pipeline register.
RMI1	9D9	PROM's MUX Inverter Bit	MI1 before it enters the pipeline register.
RMWE1	8H5	PROM's RAM Write Enable	MWE1 before it enters the pipeline register.
RPOE1	9D8	PROM's ALU Output Enable	POE1 before it enters the pipeline register.
RPZ0	8D5	PROM's RAM Page Zero	PZ0 before it enters the pipeline register.
RRA0	5K5	Read RAM Address	Microcode signal to read the RAM address counter Bus (RADD CTR BUS).
RRA01:71	8D2	PROM's RAM Address	RAM address before it enters the pipeline register.
RSEL1	3N6	Register Select	Indicates that the encoded FUNC0:2 bits are now active. An I/O operation is now active for the IDC or a disk file.
RSHFT21	12A2	RAM Shift 2nd ALU Slice	Shifts the RAM either up or down according to the ALU operation.
rSI01:31	9D2	PROM's Sequence Instruction Bits 0-3	SI01:31 before they enter the pipeline register.
RSRO01	18H1	Read/Write Serial Disk Data	Serial data shifted into the ECC circuitry during a read/write operation.

MNEMONIC	SOURCE	NAME	COMMENT
RSR00:15	18J-	Read Shift Register Bits 0-15	Accumulated bits associated with a disk file read operation.
RSTATN0	5K4	Reset Attention	Microcode signal to reset ATN0.
RSTIDL0	5N6	Reset Idle	Indicates the idle flip-flop is reset and the idle LED is off.
RWCLK1	16F7	Read/Write Clock	Read/write clock from the selected disk file.
RWGATE0,1	16G9	Read/Write Gate	Indicates the read gate or the write gate of the disk file is on.
SATN0	5M3	Set Attention	Sets the INTREQ flip-flop, thus activating ATN0 output.
SAVCRY0	13G1	Save Carry	Enables the save carry flip-flop.
SBSY01	6A4	SELCH Busy	Input from SELCH indicating SELCH is currently busy with a block data transfer.
SCHK01	6F2	Status Check	Output to SELCH to indicate a bad IDC status. (Applicable only to the new SELCH protocol.)
SCLK0A1,0B1 thru SCLK3A1,3B1	17A5-	Differential Servo Clock	Input from a disk file for the write clock (WCLK0A1,0B1 thru WCLK3A1,3B1).
SCLR01	3B9	System Clear	Input from the processor to initialize IDC logic.
SCTY1,Z1	15M-	Differential Select-Cylinder Tag	Output to a disk file to indicate that bus lines B00:09 are supplying a cylinder address.
SDATA1	16F3	Serial Read Data	Serial data, including ECC, read from a disk file.
SECTOR0,1	17M6	Sector Pulse	Sector pulses from selected disk file.
SECTOV0,1	19C6	Sector Overflow	Error condition indicating the read or write gate is up when the sector pulse is active.
SECT0A1,0B1 thru SECT3A1,3B1	17H6-	Differential Sector	Input pulse to mark the beginning of each physical sector.

MNEMONIC	SOURCE	NAME	COMMENT
SEC0	5M7	Shift ECC	Shifts the ECC register once.
SELCHBZ1	6C4	SELCH Busy	Indicates that the SELCH is currently busy with a block data transfer.
SELCHDAR1	7M7	SELCH Data Available or Requested	Indicates a received DA0 or DR0 via the SELCH.
SELCHDR0	7M6	SELCH Data Request	Indicates a data request from the SELCH.
SELCHXFR0,1	7M9	SELCH Transfer	Indicates SELCH is transferring data.
SEL01:31	15D2-	Disk File Selected	Indicates that the disk file is now selected.
SEL1	5M8	Select Pulse	Loads the disk file number (0-3) onto USEL0,USEL1.
SETIDL0	5M6	Set Idle Flip-Flop	Sets the idle flip-flop and turns on the idle LED.
SHTY1,Z1	15M-	Differential Select-Head Tag	Output to disk files to indicate that the bus lines are supplying head-select or volume-select data.
SIGN1	12E3	Sign Bit	Represents the most significant bit of the high-order slice from an ALU operation.
SI01:31	9M1	Sequencer Instruction Bits 0-3	Sequencer instruction bits input to the microprogram sequencer. See Table 4-8.
SKED0A1,0B1 thru SKED3A1,3B1	16H6-	Differential Seek End	Input from a disk file to indicate the end of a seek operation.
SKEND01:31	16L6	Seek End	Indicates the end of a seek operation at a disk file.
SKERA1,B1	14A2-	Seek Error	Indicates a seek error on a selected disk file.
SKER1	14D2	Seek Error	Indicates a seek error on a selected disk file.
SNS	6F3	Set New Sequence	Output to SELCH to indicate IDC support for the new high-speed SELCH protocol.

MNEMONIC	SOURCE	NAME	COMMENT
SNS0	6G3	Set New Sequence without Bus Switch	Output to SELCH to indicate IDC support for the new high-speed SELCH protocol, without an I/O Bus Switch. Jumping pins W1 and W2 on the IDC board for this support is not recommended.
SON1	3M3	Latched Sync On	Indicates a latched sync word received from a disk file, i.e.; a sync mark is now in the read shift register (RSR).
SPA91	10E2	Most-Significant PROM Bit 9	Most significant bit of the 10-bit PROM address which also includes PA01:81.
SR01	3J3	Status Request	Input from the processor requesting the current status (onto D080:150) of IDC or a disk file.
SR1	3K3	SR0 Received	Output resulting from SR0 input.
SSYN0	5J6	Set Sync	Microcode-generated sync return.
STCHK1	6E3	Status Check	See comment with SCHK01.
STOPDMA0	6G5	Stop DMA	Stops DMA when a partial DMA transfer occurs.
SYNCON1	7A4	Sync On	Indicates a received sync word from a disk file.
STPSLCH0	5M6	Stop SELCH Strobe	Generates SCHK0. (Applicable only to the new high-speed SELCH protocol.)
SYNC0,1	18M1, 7C2	Sync Word Detect	Indicates a sync word was detected while IDC was reading disk file data.
SYN0,1	6M4	Sync Return	Output to the processor or SELCH indicating that this IDC or an attached disk file has properly accepted and responded to a control line signal.
TACK0	4M3	Transmit Acknowledge	Output to the next IDC board to signal an interrupt acknowledgment from the processor.
TBD0	5M4	Transmitted Bus Data	Latches bus data to GPD8:15.

MNEMONIC	SOURCE	NAME	COMMENT
TESTCLR0	3B9	Test Clear	A ground signal manually placed here clears IDC logic.
TIMEOUT0,1	10M4	IDC Timeout	IDC timed out during an operation.
TSTCLK0	14F8	Test Clock	System clock for an IDC developmental system.
UNRDYLA1,B1	14A4-	Differential Unit Ready	Input from a disk file indicating its readiness for I/O.
UPWE1	12K9	Clocked RAM Write Enable	MWE1 gated with CLK341. See comment for MWE1.
UP130:230	12K8	Page Counter Bits	Binary value to identify RAM pages 0-3 of the disk file during a read.
USEL0A1,0B1 thru USEL3A1,3B1	15A2	Differential Unit-Selected Tag	Input from a disk file indicating its selection.
USEL0Y1,0Z1 and USEL1Y1,1Z1	17M4-	Differential Unit Select	Output to disk files consisting of the address number (0-3) of the disk file to be selected.
USTAGY1,Z1	15M-	Differential Unit-Select Tag	Output to disk files informing them that the unit select lines (see above) are supplying a file address.
WCLK0A1,0B1 thru WCLK3A1,3B1	17F5-	Differential Write Clock	Output to a disk file to synchronize data written to the disk file.
WDATA1	7M5	Serial Write Data	Serial data, including ECC, written to a disk file.
WDAT0A1,0B1 thru WDAT3A1,3B1	17F1-	Differential Write Data	Output data written to a disk file.
WECC0	7H5	Write ECC	Enables the ECC circuitry.
WENB0	12M9	Read/Write Enable to RAM	Selects a read/write operation over BD0:7.

MNEMONIC	SOURCE	NAME	COMMENT
WGATE1	16D9	Write Gate to Disk File	Indicates a write operation is being performed to the selected disk file.
WPROT1	14D5	Write Protected	Indicates a write-protected disk file.
WRITE1	12D8	IDC Write	Indicates this IDC is performing a write to a disk file.
WRRAM1	12K9	Write RAM Enable	Enables the IDC RAM to be written with DMA data.
WSR0:15	18E-	Write Shift Register Bits 0-15	Loaded into the WSR from BD0:7. They are written to the selected disk file.
WSR1	18F7	Write Serial Data	Serial data written to a disk file.
WTPTA1,B1	14A5-	Differential Write Protect	Input from a disk file to indicate it is in the write-protected mode.
XFERHI0	5K3	Transfer High Byte	Reads RSR08:15 to BD0:7; writes BD0:7 to WSR08:15.
XFERLO0	5K3	Transfer Low Byte	Reads RSR00:07 to BD0:7; writes BD0:7 to WSR00:07.
XFRDONE1	7J9	Transfer Done	A particular DMA transfer is complete.
XFRGPD0	3N5	Transfer General-Purpose Data	Selects the general-purpose register to be output onto the SELCH/MUX bus.
XFRREQ1	7C8	Transfer Required	DMA transfer is required.
XFRSYNCH0,1	7M8	Transfer Sync	Transfers SYN0 to the SELCH. It also clocks SELCH DMA data into the IDC.
09R08	7G3	Bit 15l Inverted	Loads data from the serial-to-parallel converter into the BD0:7 register.
09R10	7G1	DCL0 Inverted	Resets ECC clock generation.

NOTES
1. I.C. PACK LOCATIONS ARE GIVEN ON THE WIRE RUN LIST AS ROW A CFK OR R ONLY. TRANSLATE TO ACTUAL POSITIONS ON THIS ASS'Y BY USING THE FOLLOWING EXAMPLE;

RUN LIST LOCATION		SCHEMATIC ASSY LOCATION
02C 11 (COLUMN / ROW / PIN)	=	02041
ALSO – 05J01	=	05F16

2. DIMENSIONS ARE IN MILLIMETERS.
3. H DENOTES PIN 1 IN COLUMNS D F H.
4. FOR MOUNTING OF STANDARD HARDWARE SEE 16-642 DI2.
5. BEND PINS CLOSEST TO EDGE OF BOARD INWARD PRIOR TO SOLDERING.
6. CONNECTOR AREAS WHERE THE RESISTOR SIP PACKAGES ARE INSTALLED BEGIN WITH 01 RATHER THAN 00.

PUBLICATION COMMENT FORM

We try to make our publications easy to understand and free of errors. Our users are an integral source of information for improving future revisions. Please use this postage paid form to send us comments, corrections, suggestions, *etc.*

1. Publication number _____

2. Title of publication _____

3. Describe, providing page numbers, any technical errors you found. Attach additional sheet if neccessary.

   _____

   _____

   _____

4. Was the publication easy to understand? If no, why not?

   _____

5. Were illustrations adequate? _____

   _____

   _____

6. What additions or deletions would you suggest? _____

   _____

   _____

7. Other comments: _____
