
SDS 900 SERIES PROGRAM LIBRARY

PROGRAM DESCRIPTION

Page 1 of 8

Catalog No. 000011

IDENTIFICATION: Basic Utility Package IV

AUTHOR: A. W. England, SDS

ACCEPTED: 23 November 1962

COMPUTER CONFIGURATION: All 920 Systems and any 910 with typewriter.

PURPOSE: To provide a simple utility system for the SDS 910 and 920 when a more elaborate system is not required or when memory space is limited.

PROGRAMMED OPERATORS: None

STORAGE: The program occupies 288 words.

TIMING: All operations proceed at the rate of the I/O device being used. This is 15 character/sec on the typewriter, 300 characters/sec from paper tape in the photoreader and 60 characters/sec on paper tape from the punch.

USE:

1. LOADING THE PROGRAM

The system tape is in a relocatable format with a relocating bootstrap at the beginning. To load this tape, insert it in the photoreader and enter the desired starting location in the A register. Then follow the normal fill procedure. The relocating bootstrap loads into the first 32 words of memory and then loads the system program starting at the address given in the A register. When the tape is loaded, control is transferred to the program and it will address the keyboard for operational control.
2. OPERATION CONTROL CODES

All characters read by the system from the keyboard or paper tape are handled in the same manner. Digits are accumulated until a control code is read and then operated upon. There follows a description of the operations caused by the various control codes.

 - 2.1 Set Location * (asterisk), L (letter L)

The character * will be the standard set location symbol for the HELP system but the L character is allowed for compatibility with earlier systems. This character causes the previously entered five octal digits (14 bits) to be placed in

USE: (Cont.)

the location counter. The contents of the accumulate and hold words are set to zero and all flags are reset. This operation is used to set the location for loading, outputting or branching. The location setting is in the X register when the program is waiting for an input. It may be inspected by moving the compute switch to IDLE, typing a character (CR for instance) and looking in X. Move the switch to RUN before typing any further characters.

2.2 Enter Information . (period),) (right parenthesis), ▢ (lozenge)

On reading the enter symbol the program will form the word defined by the previously read characters and store it in memory in the location specified by the contents of the location counter. It then increments the location counter by 1 and clears the input accumulating words. A further description of the word formation will be found under the sections on indirect and relative addressing. The symbol right parentheses,), or lozenge, ▢, is the standard symbol for enter. Only one of these will be present on any given input preparation device and the code is the same.

2.3 Set Location to Register A, ' (apostrophe), @ (at)

The address of the temporary storage location for A is loaded into the location counter. This operation is the same as set location except that the location set is always the address of the A temporary storage word. When this code has been entered the operator can load information into the temporary A, B, and X locations in that order, by simply inputting words in the normal manner followed by the enter symbol. When either branch operation is performed to leave the system the contents of these three words are loaded into their respective registers before the branch is executed.

2.4 Step Location \$ (dollar sign)

The \$ causes the location counter to be incremented by one without storing anything in memory. It also clears and resets like the carriage return.

2.5 Start Compute at Location, J (letter J), # (hash mark), or = (equal sign)

The registers are loaded with the contents of the temporary A, B and X locations and the program executes a BRU to the location specified by the location counter. The # or = is the HELP symbol for start compute.

USE: (Cont.) 2.6 Enter Subroutine at Location, , (comma)

The contents of the temporary A, B, and X are loaded into the respective registers and a BRM is executed to the location specified by the contents of the location counter. This operation is used for entering subroutines and routines which end with a BRR. If control returns with a BRR to the system the instruction following the BRM will transfer control back to the keyboard input section.

2.7 Fill from Reader, F (letter F), : (colon)

This will cause the photoreader to be started and information will be loaded from paper tape. The format is as described for typewriter. The : (colon) is the HELP code for fill, the letter F is allowed for compatibility with earlier systems.

2.7.1 Verifying Mode, V (letter V)

This will cause the photoreader to be started and information read from paper tape as in the fill mode. However, the information from tape is not loaded but is compared with the contents of the specified memory locations. If it agrees, operation continues as usual. If it does not agree, the input stops. The A register contains the word as it was on tape, the B register contains the contents of the corresponding memory location and X contains the address of the memory location. When the halt is cleared the system will continue in the verify mode if BP 2 is set. If it is reset, control will be returned to the keyboard.

2.8 Return to Keyboard, / (slash mark)

The slash is used to indicate the end of information on paper tape and will cause an unconditional return to keyboard control. The reader is stopped.

2.9 Stop Code, # (group mark)

The Flexowriter stop code or the character # which have the same code, can be used to stop input and return control to the keyboard if BP 4 is set. If it is reset this code is ignored.

2.10 Indirect Addressing, I (letter I)

After the tag digit and the two octal digit instruction code has been read, an I may be used to set the indirect address bit in an instruction word. When this character is read the previous 9 bits are moved to the left of the word and bit 9 is set to a one. This word is placed in Hold and the accumulating word set to zero. Additional octal digits are stored in the accumulating word and when the enter symbol is read they are merged with the Hold word and the result stored in memory at the location specified. The indirect address bit will also be set if a five digit absolute address greater than 40000 octal is read.

USE: (Cont.) 2.11 Relative Addressing, + (plus) or & (ampersand)
and - (minus)

If after the tag digit, the two instruction code digits, and possibly the I code are read, a sign symbol is read, the previous digits and tags will be moved to the left and placed in Hold. The relative address tag, bit 0, will be set to one and the relative flag will be set. The accumulating word will be set to zero and each successive digit will be stored in this word until the enter symbol is encountered. The accumulated number is then added to the contents of the location counter if the sign was positive, + or &, or subtracted from the contents of the location counter if the sign was negative. This resultant address is merged with the contents of the Hold word and stored in memory at the address specified by the location counter. When giving a relative address it is not necessary to use leading zeros. The signed address field causes the resultant instruction word to be made negative regardless of whether or not the tag digit was 4 or greater. However, a tag digit of 4 or greater will not cause relative addressing on input but can be used to indicate that a word should be relativized on output.

2.12 Clear and Reset, Carriage Return, CR

The carriage return causes the accumulating and holding registers to be set to zero and all flags to be reset. The location counter is not affected.

2.13 Ignored Codes TB, SP, DL, BS

The codes for tabulate, space, backspace, and code delete are unconditionally ignored whenever read.

2.14 Output Operations

2.14.1 Output on the typewriter or punch is allowed in this utility system. In the HELP system output will be a separate module from the input routine. The output of this routine is in the same general format as that of the HELP system. Output is started by setting the location of the first word to be output using the set location operation. If output is to be stopped automatically, the ending address is then entered followed by a T for typewriter output or P for punch. The routine will then output from the first address through the ending address or until BP 1 is set. If no ending address is given, zero will be used and output will normally be terminated on BP 1 set.

- USE: (Cont.) 2.14.2 The format is the same for either typewriter or punch and it can be set for either octal mode or instruction mode. The output begins with a carriage return followed by the five digit starting address and an *. Each word is output preceded by a tab and followed by a \square or) and a carriage return. Whenever a location ending with an octal zero is encountered it is output before the tab. When output is terminated, a / will be output after the last carriage return.
- 2.14.2.1 BP 2 reset indicates octal mode. In this mode each word is output as eight octal digits.
- 2.14.2.2 BP 2 set indicates instruction mode. In this mode each word is output in the following manner:

T CDI±AAAAA

Where T indicates the three tag bits, relative, index and program operator, as one octal digit. This is followed by a space and then two octal digits for the instruction code, CD. If the addressing is indirect an I will be output after CD or a space if addressing is direct. If the address is relative, tag digit equal to 4 or greater, and BP 4 is set, the contents of the location counter are subtracted from the address portion of the instruction and the result is output as a sign and five digits of absolute value. If the addressing is non relative, tag digit less than 4, or if BP 4 is reset the sign position will be spaced over and the address output as five octal digits.

3. EXAMPLES

- 3.1 To load the octal number, 01234567 in location 347:

00347*01234567. CR

- 3.2 To load an instruction to add a word whose address is in a word 4 previous to the instruction itself which is at 7046:

07046*55I-4)CR

In memory this would appear as 45547042. If an instruction mode typeout were called for it would appear as:

07046* 4 55I-00004)CR

when BP 4 is set and as:

07046* 4 55I 07042)CR

when BP 4 is reset.

USE: (Cont.) 3.3 To initiate the punchout of words 542 through 556:

00542*00556P

4. RECOVERY OF PROGRAM CONTROL

If control is taken from the system and the operator wishes to return to the system using console operation there are two methods:

- 4.1 If location 0001 has not been destroyed by some other program operation then control can always be recovered by the following procedure:
- a. Move COMPUTE switch to IDLE.
 - b. Press START button.
 - c. STEP COMPUTE switch.
 - d. Move COMPUTE switch to RUN.
- 4.2 If location 0001 has been destroyed control can be recovered by inserting in the C register and executing a BRU to the address originally entered into A when the system was loaded. After this location 0001 will be restored and control will go to the system which will then address the keyboard.

5. SUMMARY OF OPERATIONS

| OPERATION | CODE |
|--|-------|
| Set location | * L |
| Enter word and advance location counter | □) . |
| Set location to register A | ' @ |
| Step location | \$ |
| Start compute at location | J # = |
| Enter subroutine at location | , |
| Fill from photoreader | F : |
| Verify from photoreader | V |
| Stop fill or verify and return to keyboard | / |
| " " " " " " " " BP 4 SET # (SC) | |

| USE: (Cont.) | OPERATION | CODE |
|--------------|--|---------------|
| | Set tag field for program operator | First Digit 1 |
| | Set tag field for index | First Digit 2 |
| | Set tag field for program operator and index | First Digit 3 |
| | Set tag field for relative addressing | First Digit 4 |
| | Set tag field for program operator and relative addressing | First Digit 5 |
| | Set tag field for index and relative addressing | First Digit 6 |
| | Set tag field for program operator, index, and relative addressing | First Digit 7 |
| | Set indirect address tag | I |
| | Set relative forward | +& |
| | Set relative backward | - |
| | Start typeout octal format BP 2 RESET | T |
| | Start Typeout absolute instruction format, BP 2 SET, BP 4 RESET | T |
| | Start Typeout relative instruction format, BP 2 SET, BP 4 SET | T |
| | Start punch octal format, BP 2 RESET | P |
| | Start punch absolute instruction format, BP 2 SET, BP 4 RESET | P |
| | Start punch relative instruction format, BP 2 SET, BP 4 SET | P |
| | Clear and reset | CR |
| | Ignore | TB |
| | Ignore | SP |
| | Ignore | BS |
| | Ignore | DL |

METHOD:

Each digit or character is read into memory. A table search is then performed to determine if this code is a special or control code. If it is, then a transfer of control is made to the beginning of the appropriate control routine. If it is not found in the table it is assumed to be an octal digit and the least significant three bits are shifted into the right end of an accumulating word. Whenever a control code is encountered which uses previous data it picks this up from the accumulated word.

In the process of inputting an instruction the tag and instruction code are accumulated as three octal digits and then if an I is input it causes the contents of the accumulated word to be transferred to the hold word and shifted to the left end of the word. Bit 9 of this hold word is then set to a one and a hold flag is set. A plus or minus sign will cause a similar operation. If the hold flag is reset when the sign is encountered the accumulated word is shifted and transferred to hold and a relative flag as well as the hold flag, is set. If the hold flag was set when the sign was encountered only the relative flag is set. In either case bit 0 of the hold word is then set to one.

Additional digits are now accumulated until the enter symbol is encountered. If the hold flag were reset the contents of the accumulated word would be stored at the address specified by the location counter. However, if the hold flag is set and the relative flag reset the lower 14 bits of the accumulated word are merged with the contents of hold and then stored. When the hold is set and the relative flag is set the contents of the accumulated word are added or subtracted, depending on the sign that set the relative flag, to the location counter and the result merged with the contents of hold. After this the word is stored, all flags are reset, hold and accumulate are cleared, and the location counter is incremented by one.

In the case of the output operations the starting address is in the location counter and the ending address in the accumulated word. Since the set location operation clears the accumulated word the ending address will be zero if no other address is input. The output proceeds to increment the location counter after each word is output and compares it to the accumulated word. When they agree it terminates output and returns control to the input section.

IDENTIFICATION: DEBUG

AUTHOR: R. C. Shepardson, SDS

ACCEPTED: January 11, 1964

COMPUTER
CONFIGURATION: Any SDS 910 or 920 computer

PURPOSE: This is a relocatable routine which will aid the user in debugging.

Functions which may be performed by this routine are:

1. Make in-core corrections or insertions.
2. Dump selected memory areas on the printer or typewriter.
3. Perform snapshots at selected points.
4. Allow the user to seize control at selected points.
5. Perform masked memory searches.

PROGRAMMED
OPERATORS: None

STORAGE: This relocatable routine requires 419_{10} (643_8) locations. Locations 2-14₈ are used for temporaries. The loader uses 1-63₈. The standard constants in 23₈-27₈ are used. The loader will store in location 1 a BRU to the load origin.

TIMING: I/O device speed.

USE: LOADING

The routine is preceded by a relocatable loader which requires the following loading procedure:

1. Set the A register to the desired load origin.
2. Set breakpoint switches (see Breakpoint Settings).
3. Perform standard fill procedure.

USE: (cont.)

BREAKPOINT SETTINGS

BP1 - Reset - Console typewriter input
Set - Card reader input

BP2 - Reset - Console typewriter output
Set - Buffered printer output

BP3 - Reset - Single space output
Set - Double space output

BP4 - Reset - No seizure by user at each snapshot
Set - Transfer control to user after each snapshot

CONTROL

Control may be transferred to DEBUG by branching to the load origin.

Another alternative is to execute a:

BRM load origin + 16

which will save and print the contents of the P, A, B and X registers, after which the DEBUG routine will seize control. An exit request will restore the contents of the registers and return.

The debugging functions available are listed below:

1. NOP Request

Input: N location list.

This request will store NOP instructions in each of the locations specified in the location list. Control is then returned for the next request.

2. ALTER Request

Input: A location, alter list.

This request will store the octal words specified by the alter list into monotonically increasing locations.

Contiguous commas leave the appropriate location(s) unchanged.

USE: (cont.)

The following example best illustrates the use of this request:

A2075, 7602100, 3502012, 102066, 17, , 77, 27/3, 77777777.

The above requests alters memory as follows:

| | |
|------|------------|
| 2075 | 07602100 |
| 2076 | 03502012 |
| 2077 | 00102066 |
| 2100 | 00000017 |
| 2101 | unchanged |
| 2102 | 00000077 |
| 2103 | } 00000003 |
| thru | |
| 2130 | |
| 2131 | 77777777 |

Card input requests will not allow a block alteration (as in locations 2103 thru 2130 above) except as the last alteration on the card because of timing restrictions.

3. INSERT Request

Input: I location, octal instruction list.

This request will cause the list of octal instructions to be logically inserted following the location specified.

The following example will illustrate the method used:

I 403, 27700002, 3704013.

| <u>Before</u> | <u>After</u> |
|---------------|--------------|
| 403 07104013 | 001 BBBB |
| BBBBB | 07104013 |
| BBBBB+1 | 27700002 |
| BBBBB+2 | 03704013 |
| BBBBB+3 | 00100404 |

Any insertions use memory immediately following the DEBUG Routine (designated as BBBB above).

Caution should be used in making insertions because the instruction at the location of the insertion will be moved.

USE: (cont.)

4. DUMP Request

Input: D block.

This request will dump onto the buffered printer or the console typewriter the contents of the memory block specified and return control for the next request.

The format of the output is eight octal words per line. If all numbers on one or more lines are identical, all lines except the first will be suppressed.

Example:

D1400-1427.

or

D1400.

Appendix II contains a sample of the dump output.

5. SNAP SHOT Request

Input: S location, block list.

This request will insert at the location specified a calling sequence which, when executed, will print on the console typewriter or printer the location of the snapshot and the contents of the A, B and X registers and the contents of memory blocks specified in the block list. Furthermore, if BP4 is set, control will be transferred following the snapshot to the DEBUG routine to enable the user to make additional requests at that point. Otherwise, control returns as usual to the main program.

Example:

S 4017, 200-220, 0, 740-743.

6. EXIT Request

Input: X

When the user has seized control during a snapshot (BP 4 set) this request will cause the A, B and X registers to be restored and control to be returned to the point where the snapshot occurred.

USE: (cont.)

7. BRANCH Request

Input: B location.

This request restores the A, B and X registers and then performs a branch to the specified location.

8. RESTORE Request

Input: R location list.

This request will logically remove the insertion (including snapshot insertion) made at the location specified. Control is then returned for the next request.

Example:

R 1260, 3102, 4017.

9. TOGGLE Request

Input: T toggle list.

This request enables the user to reassign or eliminate the breakpoint toggle tests within the DEBUG routine in the event that the breakpoint toggle settings conflict with his program.

The toggle list consists of 1 to 4 characters. The i^{th} character corresponds to the option normally associated with the i^{th} breakpoint toggle as follows:

- a. 1 - Assign breakpoint toggle 1 (to the option normally associated with the i^{th} breakpoint toggle).
- b. 2 - Assign breakpoint toggle 2
- c. 3 - Assign breakpoint toggle 3
- d. 4 - Assign breakpoint toggle 4
- e. S - Assume the breakpoint toggle normally associated with the i^{th} option set
- f. R - Assume the breakpoint toggle normally associated with the i^{th} option reset

Example:

T4RRS.

T12S.

USE: (cont.)

10. LOOK Request

Input: L lower bound, upper bound, value, mask.

This request searches the memory area designated by the bounds for all locations whose contents are equivalent to the value specified using the mask.

INPUT COMMENTS

Both forms of the space character and the carriage return character are completely ignored.

\$ will cause the current request to be immediately terminated. The next request is then read.

. designates the end of each request except the EXIT request.

Appendix I contains a rigorous description of the syntax of the requests.

MODIFICATIONS

The variable BBB in the DEBUG Routine addresses the last location used of the insertion block. The user may wish to change the memory area used for the insertion block by altering the contents of BBB which is in load origin +570₈.

METHOD:

Not Applicable.

The meta-language defining the syntax is similar to that which is used in the definition of the ALGOL syntax.

```

<nop request>      ::=  N <location list> .
<alter request>   ::=  A <location> , <alter list> .
<insert request>  ::=  I <location> , <instruction list> .
<snapshot request> ::=  S <location> , <block list> .
<dump request>    ::=  D <block> .
<restore request> ::=  R <location list> .
<branch request>  ::=  B <location> .
<exit request>    ::=  X
<toggle request>  ::=  T <toggle list> .
<search request>  ::=  L <location> , <location> , <octal number> ,
                       <octal number> .

<location list>   ::=  <location> , <location list> | <location>
<instruction list> ::=  <octal number> , <instruction list> | <octal number>
<alter list>      ::=  <alter entry> , <alter list> | <alter entry>
<alter entry>     ::=  , | <octal number> / <octal number> | <octal number>
<block list>      ::=  <block> , <block list> | <block>
<block>           ::=  <location> - <location> | <location>
<toggle list>     ::=  <toggle designation> <toggle list> | <toggle designator>
<toggle designator> ::=  1 | 2 | 3 | 4 | R | S

```

<location> is 1 to 5 octal digits.

<octal number> is 1 to 8 octal digits.

Spaces (60 or 12) and carriage return characters are ignored.

\$ will immediately terminate a request.

APPENDIX II

SDS 900 SERIES PROGRAM LIBRARY

PROGRAM DESCRIPTION

Page 1 of 4

Catalog No. 020012

IDENTIFICATION: Paper Tape Reproducer Program

AUTHOR: A. W. England, SDS

ACCEPTED: 15 August 1963

COMPUTER CONFIGURATION: Any 910 or 920 with punch, reader, and typewriter.

PURPOSE: To reproduce binary paper tape. Only tapes which have an integral multiple of four characters in each block can be reproduced with this program.

PROGRAMMED OPERATORS: N/A

STORAGE: The program occupies 270_{10} locations from 200g to 616g. The next 512 words are reserved for record table storage. The remainder of memory is used to hold the records of the tape to be reproduced.

TIMING: All operations proceed at the maximum rate of either the punch (60 characters per second) or the reader (300 characters per second).

USE:

- I. TO LOAD PROGRAM
 - A. Insert tape in reader.
 - B. With COMPUTE switch in IDLE press START button.
 - C. Move COMPUTE switch to RUN.
 - D. Set BP 1.
 - E. Raise and lower FILL switch.
- II. TO REPRODUCE A TAPE

A tape may be reproduced by first reading it, then verifying it, punching one or several copies of it, and finally verifying the copies. Each of these functions of the program will be described below. Upon

USE: (Cont)

completion of each function, control will be returned to the operator via the typewriter, which is signified by the illuminated typewriter light and the presence of 000001 in the I/O address lights.

A function is initiated by typing one control letter; R, V, or P. The letter P may be preceded by a number to indicate the number of copies to be made.

Below is the procedure for reproducing tapes:

A. Read

1. Place the tape to be reproduced in the reader.
2. RESET BP 1.
3. Type R.
4. When the tape runs out of the reader, SET BP 1.

B. Verify

1. Place the tape to be verified in the reader.
2. Reset BP 1.
3. If there is only one copy to be verified or if there are several copies to be verified one at a time, RESET BP 2.
4. Type V. The tape will be read and verified. If an error is found, the reader will stop at the end of the copy and the program will type VERIFY ERROR.
5. If several copies are to be verified at once, SET BP 2 and type V.

When the tape runs out of reader or onto the the last length of trailer, SET BP 1.

C. Punch

After the tape has been read and verified, it may be punched as follows:

USE: (Cont)

1. If the tape is to have a short leader RESET BP 3. If it is to have a long leader (for mounting on a reel) SET BP 3.
2. If the tape is to have a short trailer, RESET BP 4. If it is to have a long trailer (for mounting on a reel), SET BP 4.
3. If only one copy is to be made, RESET BP 2 and type P. When the copy has been punched the light will come on.
4. If more than one copy is to be punched, SET BP 2 and type a carriage return, then the number of copies to be made, and the letter P. The program will punch the desired number of copies and stop. If it appears that there is not sufficient paper tape to punch all the copies, BP 2 may be RESET and the program will stop after the copy it is then punching.

D. Verify New Tape

Follow procedure as outlined in B above.

III. ERRORS

A. Reading

1. If a Read error occurs, the program will stop the tape and type READ ERROR.
2. If the tape to be reproduced exceeds the capacity of memory, the program will stop the tape and type STORAGE FULL.
3. If the tape to be reproduced has more than 512 blocks on it, the program will stop the tape and type TABLE FULL.

B. Verifying

If a copy fails verification, the program will stop the tape after that copy and type VERIFY ERROR.

IV. BREAKPOINTS

| <u>BP NO.</u> | <u>RESET</u> | <u>SET</u> |
|---------------|---------------|--------------|
| 1 | Normal | Stop |
| 2 | One | Many |
| 3 | Short Leader | Long Leader |
| 4 | Short Trailer | Long Trailer |

METHOD:

When a tape is read, the program records the gap length preceding the punched information and stores this in the record table. It also maintains the starting addresses of each record read. When Breakpoint 1 is set, the read is stopped and an end indicator is inserted in the table.

Verify is similar to read except that no attempt is made to verify the length of gaps. Each word of the record read from tape is compared with the corresponding word in memory. Any disagreement is indicated.

Punching utilizes the gap count generated during read to reproduce the proper length gaps between records. Each record is punched from memory with gaps as required. At the beginning and end of the tape the program punches either short (3 feet) or long (10 feet) leader depending on the settings of Breakpoints 3 and 4.

IDENTIFICATION: FORTRAN Memory Save

AUTHOR: Robert C. Shepardson, SDS

ACCEPTED: November 15, 1963

COMPUTER

CONFIGURATION: Any 910 or 920 computer with paper tape reader and punch.

PURPOSE: To punch a self-loading paper tape representing the FORTRAN Program which is in core and optionally to punch any of the following:

1. The FORTRAN variables
2. COMMON
3. Run-Time.

PROGRAMMED

OPERATORS: None.

STORAGE: 360 words (relocatable).

TIMING: Paper tape punch speed.

USE: Breakpoint switches 1, 2, and 3 are used as follows to designate the options desired:

BP 1 Reset - Don't punch variables
 Set - Punch variables

BP 2 Reset - Don't punch COMMON
 Set - Punch COMMON

BP 3 Reset - Don't punch Run-Time
 Set - Punch Run-Time

The routine is on a self-loading tape which loads itself into the topmost 360_{10} locations of eraseable storage. If there are not at least 360_{10} locations of eraseable storage available (as indicated by (72_8) in the Run-Time), the tape stops and the computer halts at location 16_8 . The operator may then place a starting address P in the A register and clear the halt; the routine will then load itself into locations P through $P+357_{10}$.

USE: (Cont)

RELOADING

The procedure for resuming execution of the FORTRAN program (dumped on paper tape) depends upon whether or not the BP 3 option (punch Run-Time) was invoked.

A. Self-loading tape does not contain the Run-Time

1. Load FORTRAN Run-Time
2. Load self-loading FORTRAN program
3. Branch to location 400_8 .

B. Self-loading tape includes the Run-Time

1. Load self-loading FORTRAN program. The computer will type "LOADING COMPLETE" and halt.
2. Clear the halt.

METHOD:

After being loaded, the FORTRAN Memory Save program will punch out a loader followed by the FORTRAN program and optionally the variables, COMMON and Run-Time. The following table defines precisely the locations which are punched:

| | | |
|---|-------------------------------|---|
| Unconditionally | 71 thru 75_8 | EOADR, EOSIZE, EOTAG, EOIND, SENWRD |
| | 160_8 thru 247_8 | User POPS and System Routine Linkages |
| Program without variables (BP 1 reset) | $(400_8)-10_8$ thru (EOADR)-1 | but not including the dummies, temporaries, equivalenced variables, arrays and scalars (see Memory Layout at Run-Time, FORTRAN Operators Manual). |
| Program with variables (BP 1 set) | $(400_8)-10_8$ thru (EOADR)-1 | |

| | | |
|----------------|------------------------|---|
| METHOD: (Cont) | COMMON (BP 2 set) | (EOADR) + (EOSIZE) thru Top of Memory |
| | Run-Time (BP 3 set) | 1 76 ₈ thru 157 ₈ 250 ₈ thru (400 ₈)-10 ₈ |

PROGRAM DESCRIPTION

Page 1 of 4

Catalog No. 034001

IDENTIFICATION: Card Reader Test Program

AUTHOR: F. Valadez, SDS

ACCEPTED: 10 May 1963

COMPUTER
CONFIGURATION: Any SDS 920 or SDS 910 with a typewriter, and SDS
Model 9151 card reader.

PURPOSE: To provide an acceptance test for the SDS 9151 card
reader.

PROGRAMMED
OPERATORS: None

STORAGE: Octal locations 200-613 (268 words).

TIMING: Not applicable.

USE: The Card Reader Test Program consists of a self-
loading paper tape and a special 64-card test deck.
The card deck is sequentially numbered and must be
in correct order to run the test.

To perform the card reader test, proceed as follows:

1. Load the program by normal Fill procedure. When
the program is loaded the computer will halt.
2. Check the test deck for correct sequencing of cards.
3. Select either the binary or Hollerith test by means
of Breakpoint Switch 1.

BP 1 set: Hollerith read test

BP 1 reset: Binary read test

4. Load the test deck and turn on the EOF ON
indicator.
5. Clear the computer halt to start the test.

Normal Run

If the test deck reads through successfully one of the
following messages will be typed out, depending on the
mode selected: "Binary test complete" or "Hollerith

JSE: (cont.)

test complete". The computer will then halt. At this time the test deck may be reloaded and the program repeated by clearing the halt.

Note: During the Hollerith read test, the VALIDITY CHECK light will be on continuously.

Error Indication

If an error occurs during the test, a message will be typed and the computer will halt. If an error halt occurs, the entire program must be restarted.

The following error messages are possible:

1. BIN check error:

The binary check character (52522525) read from columns 1 and 2 of the last card is not correct. The A register contains the pattern read from the card while the B register contains the value which should have been read.

2. HOL check error:

Either the Hollerith character (T) read from column 3 is not correct or a validity check has occurred while reading it. The A register contains the binary-coded value of the Hollerith character read from the card while the B register contains the value which should have been read.

3. IDN check error:

The identification number read from the last card does not sequentially follow that of the preceding card. The A register contains the sequence number read from the card while the B register contains the expected sequence number.

4. Error in column N:

The information read from the particular card column is not correct. For the binary test, the A register contains the binary pattern read from the card, while the B register contains the pattern which should have been read. For the Hollerith test, the A register contains the Hollerith value read from the card, while the B register contains the binary pattern that should be in that card column.

USE: (cont.) 5. Signal not present:

At certain places, the program tests for the presence of the following signals:

Card Reader ready to feed (SKS 12006)

Card Reader ready to read one column (SKS 14006)

The program will loop before continuing until the particular signal is received. Upon terminating the test, the Card Reader end-of-file signal (SKS 11006) is tested.

METHOD:

Each card in the test deck contains the following fields:

1. Binary check character (columns 1 and 2.)
2. Hollerith check character (column 3).
3. Identification number (columns 4 and 5).
4. Test data (columns 8 through 71)

Columns 6, 7, and 72-80 are blank.

The test data contains every possible columnwise combination of punches arranged in ascending binary order. Column binary information is read from top to bottom, where the 12-row is the most significant bit and the 9-row is the least significant bit.

Each field on the card is read and interpreted for correctness as follows:

1. Columns 1 and 2 are read in the binary mode and form a check character whose octal value is 52522525.
2. Column 3 is read in the Hollerith mode and is the letter "T". The octal value is 63.
3. Columns 4 and 5 are read in Hollerith and converted to binary by the program to form the card identification number. This number is then checked for correct sequence.
4. Binary test: Columns 8 through 71 are read in the binary mode, one column at a time. Each column is checked against an internal binary counter. Between columns, the W buffer is disconnected and the program waits for Card Reader ready (SKS 12006) before reading the next column.

METHOD: (cont.)

Hollerith test: Columns 8 through 71 are read in the Hollerith mode, one column at a time. The octal value read from a particular column is used to select a binary pattern from a table. This value is compared with the internal binary counter pattern. The two patterns should match for valid Hollerith characters and not match for non-valid Hollerith characters. The validity error signal should be set for non-valid Hollerith characters.

PROGRAM DESCRIPTION

Page 1 of 3

Catalog No. 034002

IDENTIFICATION: Card Punch Test Program Package

AUTHOR: F. Valadez, SDS

ACCEPTED: 9 May 1963

COMPUTER

CONFIGURATION: SDS 920 or SDS 910 with SDS model 9156 card punch system. For the verify test, an SDS model 9151 card reader and a typewriter are required.

PURPOSE: To provide an acceptance test for the SDS model 9156 card punch system.

PROGRAMMED

OPERATORS: None.

STORAGE: 172 words.

TIMING: N/A

USE: The test package contains two acceptance tests whose outputs can be verified on-line, plus a special service test that can be used for checkout. The acceptance tests are selected by breakpoint switch settings, while the service test is entered by executing a branch instruction in the C register.

The test package tape is self-loading by normal Fill procedure. After the tape has been loaded, the computer will halt. At this time, set the breakpoint switches as outlined under the description of the desired test, and clear the halt to start the test.

A. TEST 1 - SINGLE CHARACTER PER CARD

This test punches the entire Hollerith character set, one character per card. The same character is repeated in columns 1-80 of each card. The following punch signals are tested: SKS 12046, SKS 14046.

To select this test, set Breakpoint Switch 1; reset Breakpoint Switches 2, 3, and 4.

When the test is completed, the computer will halt. The test can be repeated by clearing the halt.

USE: (cont.) B. TEST 2 - ENTIRE CHARACTER SET ON CARD

This test punches the entire Hollerith character set on every card, in rotating fashion. Thus, every Hollerith character will be punched in every card column. The following punch signal is tested: SKS 14046.

To select this test, set Breakpoint Switch 2; reset Breakpoint Switches 1, 3, and 4.

When the test is completed, the computer will halt. The test can be repeated by clearing the halt.

C. SERVICE TEST

This test punches the pattern in the A register across the entire card. Every fourth column will contain the same information.

Before starting the test, enter the pattern to be punched in the A register. To start the test, reset Breakpoint Switch 1 and execute a BRU 342 (00100342) from the C register.

Punching will start and continue until Breakpoint Switch 1 is set. When the switch is set, the computer will halt. To restart the test, raise BP 1 and clear the halt.

To leave the service routine and return to the acceptance test, execute a BRU 200 (00100200) from the C register.

D. VERIFICATION

This test can be used to verify the cards punched by Test 1 or Test 2 only. There is no verification for the service test.

To use this test, first run either Test 1 or Test 2. When the punch test is completed, set Breakpoint Switch 3 in addition to the Breakpoint setting for the particular punch test. Load the cards into the reader and clear the halt. The information on the cards will now be read and checked for correctness.

If the information is all correct, the message "Verify Complete" will be typed. If an error is detected, "Verify Error" will be typed and the computer will halt. The last card read will be in error. It is not possible to continue the verify test. However, it can be restarted from the beginning by reloading the card deck and clearing the halt.

METHOD:

An initial card image is formed and stored in a buffer area. For the acceptance tests, the image is modified between cards; the service test does not alter the initial image.

The verify test generates and modifies the card images, and compares the results against the punched cards.

SDS 900 SERIES PROGRAM LIBRARY

PROGRAM DESCRIPTION

Page 1 of 3

Catalog No. 044001

IDENTIFICATION: 15 KC Magnetic Tape Test Using Interrupt with Interlace Option

AUTHOR: Richard S. Resnick, SDS

ACCEPTED: 3 December 1962

COMPUTER CONFIGURATION: Any SDS 910 or SDS 920 with one 9140 or 9145 Magnetic Tape Unit.

PURPOSE: This program aids in testing the input/output capabilities of the 9140 or 9145 Magnetic Tape Unit using Interrupt and/or Interlace.

PROGRAMMED OPERATORS: None

STORAGE: Location 00033, locations 00200 thru 00377, and locations 01000 thru 02000 for data storage.

TIMING: Not applicable.

USE: The Interim Utility Package (II, III or IV), Catalog Numbers 090001 or 000011, must be in memory and is used to load this program. To load this program, the program is placed in the reader and the "F" key on the typewriter is depressed. Loading is then automatic.

This program tests the ability of the computer to output blocks of information to one tape unit by normal output methods using interrupt or by interlacing the information to the magnetic tape unit. The program also tests the ability of the computer to read information from the magnetic tape unit under the above-mentioned circumstances. The program essentially reads or writes the same word N times per block. The block length and word are initial parameters and do not change unless reloaded.

The Breakpoints have the following meaning:

Breakpoint 1 set = Repeat Test
Breakpoint 2 reset = Return Control to the Typewriter
Breakpoint 2 set = No Halt on Errors
Breakpoint 2 reset = Halt on errors
Breakpoint 3 set = Read (Input from Magnetic Tape)
Breakpoint 3 reset = Write (Output to Magnetic Tape)
Breakpoint 4 set = Interlace
Breakpoint 4 reset = No Interlace

USE: (Cont.)

The program operates under control of the Interim Utility Package. Several operations are performed by special subroutines. To perform an operation, the operator must address the desired operations subroutine from the keyboard by typing the operation's starting address, a star (*) and then a comma. The following is a list of the operation and their starting address:

LOAD A AND B = 'AAAAAAAA. BBBB BBBB.

This loads the A register with the desired block length and the B register with the desired data word.

SET-UP = 350* , (A = Number of words per block)
(B = word)

The program sets up the block length and word. It also initializes the other subroutines. The Pot constant is set up by this program.

CONTROL = 200* ,

This program performs the actual communication, one block per entry, in compliance with the Breakpoint settings.

REWIND = 320* ,

This program rewinds the tape to the beginning.

ERASE = 340* ,

This program erases 13 3/4 feet of tape.

BACK-UP = 330* ,

This program backs up one block per entry. Continuous back-up can be obtained by setting Breakpoint 1.

There are only two error halts:

Location 240 = Buffer Error

Location 272 = Data Error (A = Bits that failed)
(B = Location of error)

USE: (Cont.)

Example of Usage

'40. 12345671. 350 * , (Set BP 1, 4) 320 * ,
340 * , 200 * , (reset BP 1 after a few seconds)
(set BP 1, 3, 4) 330 * , (reset BP 1) 200 * , -

Set count to 32_{10} and word to 12345671.

Rewind tape to beginning.

Erase 13 feet.

Store 12345671, 32 words per block into magnetic tape
Interlace.

Back tape up.

Read magnetic tape unit and test results.

METHOD:

Not applicable.

PROGRAM DESCRIPTION

Page 1 of 10

Catalog No. 044004

IDENTIFICATION: Multi-Magnetic Tape System Exerciser

AUTHOR: A. W. England, SDS

ACCEPTED: 24 June 1964

COMPUTER CONFIGURATION: All 920, 925, and 930 systems, or any 910 systems with a typewriter, which have one to sixteen tape units attached to the W and/or Y buffers. No interlace is required and the tapes may be of any density and speed within the limitations of the buffer to which they are attached.

PURPOSE: This program is designed to exercise from one to sixteen tape units by first writing random numbers in random length records on all tapes under test and then reading these records back and comparing them with the numbers written. An attempt is made to tabulate and output all useful information concerning the errors made, if any, the mode of operation of each unit, and the number of passes over the tape.

STORAGE: The program occupies the first 1155 words of memory. The remaining memory may be used for test record storage.

TIMING: The program requires approximately 20 minutes to write or read a full reel (2400 feet) of tape.

USE:

- 1.0 LOADING

Place tape in reader and FILL. When loading is complete the light on the typewriter will light if no loading error occurred.
- 2.0 KEYBOARD CONTROL

When the keyboard light is on, the operator has control over the program. By actuating various keys he may set the test parameters, inspect results or start the exerciser test running.
- 2.1 REGAINING KEYBOARD CONTROL

Control may be returned to the keyboard mode at any time by moving the RUN-IDLE-STEP switch to IDLE, pressing the START button, and moving the switch first to STEP then to RUN.

USE: (Cont)

3.0 CONTROL FUNCTIONS

The following list contains the call letters for the various functions which the program will perform. These may be typed anytime the typewriter light is lit.

3.1 SELECT UNITS, "U"

The units to be exercised are selected by first typing the letter "U" followed by the several unit numbers separated by commas and finally a carriage return. After the last unit number followed by a comma is entered a carriage return must be given to terminate the unit select operation. Units on the W buffer are numbered 0-7 and on the Y buffer 10-17₈.

3.2 SET STARTING RANDOM NUMBER, "N"

The initial random number is set by first typing the octal number desired (up to 8 digits) and then the letter N. The number being typed can be set to zero by typing a carriage return.

3.3 SET MAXIMUM FILE LENGTH, "M"

The maximum number of records in the test file is set by typing the desired number of records in octal followed by the letter M. If the entire 2400 foot reel is to be written a maximum count of 10000₈ or greater should be sufficient.

3.4 SET MAXIMUM RECORD LENGTH, "L"

The maximum number of words in a record is set by typing the limit in octal followed by the letter L. If the specified maximum is less than or equal to 8 or greater than the maximum memory available then the maximum length is set equal to the memory available.

3.5 MODE SELECT

The recording mode, either BCD or Binary is selected by typing the appropriate letter.

3.5.1 Select Binary Mode, "B"

Typing the letter B will cause the appropriate EOM instructions to be converted to the binary mode of operation.

USE: (Cont) 3.5.2 Select BCD Mode, "D"

Typing the letter D will cause the EOM instructions to be set for BCD operation.

3.6 SELECT OUTPUT MEDIA

The output of the various messages and counters during the operation of the program can be on either the on-line typewriter or on paper tape for off-line listing. This is controlled by typing the appropriate letter before starting.

3.6.1 Select Typewriter Output, "T"

The typewriter is selected by typing the letter T.

3.6.2 Select Punch Output, "P"

The punch is selected by typing the letter P.

3.7 INITIATE TAPE OPERATION

After the appropriate parameters have been set the tape exercise operation may be initiated. There are three ways in which this may be done. If nothing has been recorded then the exercise must be begun with a START WRITE. However, once a file of information is written on tape and the program is stopped the other two starts can be used.

3.7.1 Start Write, "S"

To begin the exercise operation, type the letter S. The program will rewind all units and start to write a random number test file on the selected units.

3.7.2 Continue Operation, "C"

Once the exercise operation has been stopped with Breakpoint 1 (see section 4.1) it can be resumed from the point at which it was stopped by typing the letter C.

3.7.3 Restart Read, "R"

If during a read pass the program is stopped and the operator would like to reread the file from the beginning he can type the letter R to restart the read pass.

3.8 OUTPUT OPERATIONAL STATUS, "O"

The operator can inspect the status of the operation at anytime by stopping the program with Breakpoint 1 (see section 4.1) and typing the letter O. The program will then type out the status of the exercise operation as follows:

USE: (Cont) 3.8.1 Type of Pass

It types READ or WRITE depending on the type of pass in progress.

3.8.2 Mode of Operation

It then types the mode of operation, either BINARY or BCD.

3.8.3 Unit

The UNIT NO. of the tape unit currently being addressed is typed.

3.8.4 Program Counters

After this information the program will type a table of 17 counters each identified by a three or four character symbol. These symbols and their definitions follow:

MRC Maximum Record Count. This is the octal number entered with the M key at the start of the exercise operation.

MRL Maximum record length currently being used.

WRC Write Record Count. If in a write pass this indicates the number of records written. In a read pass it indicates the total number written in the previous write pass.

RRC Read Record Count. This indicates the number of records read during a read pass.

WPC Write Pass Count. The number of write passes completed.

RPC Read Pass Count. The number of read passes completed.

WEC Write Error Count. The number of write errors that have occurred.

RWEC Rewrite Error Count. This number of rewrite errors.

PREC Permanent Read Error Count. The records that were read bad 10 times.

CPEC Character Parity Error Count. The number of character parity errors that have occurred since the start of the exercise.

| | | |
|-------------|--|---|
| USE: (Cont) | LPEC | Longitudinal Parity Error Count. The number of longitudinal parity errors that have occurred. For each read try only one character or longitudinal parity can be counted and character parity has priority. |
| | WCEC | Word Count Error Counts. The number of word count errors that have occurred. A word count error occurs if the record read is longer or shorter than the record expected. |
| | CH1 CH2 CH3 CH4 CH5 CH6 | Errors in Channels 1-6. Channel 1 is the most significant bit, channel 6 the least. These counters are also output whenever a read error occurs if Breakpoint 2 is RESET. After a read error output they are cleared. |

4.0 BREAKPOINT SWITCHES

The four Breakpoint switches are used to change the status of the program while it is running. These functions are as follows:

4.1 BREAKPOINT 1

RESET: Normal

SET: Stop operation. After almost every tape operation there is a STOP point. If Breakpoint 1 is set the program will mark its place and return to the keyboard control mode. Operation can be continued by typing the letter C.

4.2 BREAKPOINT 2

RESET: Output counters and messages whenever the normal output situation occurs.

SET: Skip the output of messages and counters. This will inhibit all output except the OUT OF SYNC message and the FILE PROTECT ON message.

4.3 BREAKPOINT 3

RESET: At the end of a read pass go on to another write with new random numbers.

SET: At the end of a read pass go back and reread the same file again.

4.4 BREAKPOINT 4

RESET: Run without halts.

SET: Halt on a write error or at the end of a read pass. Clearing these halts will allow the program to continue.

USE: (cont.) 5.0 MESSAGES

The program will type or punch status messages at various times in the operation of the exercise. These are described below:

5.1 END OF PASS

At the end of a write or read pass the output will be either WRITE or READ, PASS DONE. This is followed by a carriage return and the following two lines:

```
WRITES  READS  WRITE ERR  REWRITES  BAD READS  
aaaaaaaa bbbbbbbb cccccccc dddddddd eeeeeeee
```

where the a's represent the number of write passes in octal, the b's the number of read passes, the c's the number of write errors which have occurred, the d's the number rewrite errors, and the e's the number of records which were read erroneously 10 times.

5.2 REWRITE ERROR

If a write error is detected the program erases backward over the record and attempts to rewrite it. If this second attempt is also in error the program outputs the following counter titles:

```
WRITE PASS RECORD NO. WRITE ERRS REWRITE ERRS
```

This is followed on the same line by the mode of operation (Binary or BCD) and the unit number. On the next line below the appropriate title it outputs the write pass count, the write record number count, the write error count and the rewrite error count. All counts are in octal.

5.3 READ ERROR

If a read error occurs the program rereads the record nine more times and then outputs the read pass, record number, mode, and unit number. This is followed by a carriage return, the message, READ ERROR another carriage return and then nine, eight-octal-digit counters which represent the following quantities (from left to right): character parity error count, longitudinal parity error count, word count error count, errors in channel 1, channel 2, etc., to channel 6. On the next line the program outputs a good or bad message for each of the 10 reads. This consists of the letter G if the read was correct or B if the read was incorrect.

USE: (cont.)

For example:

B G G G B G G G G G

Indicates that the first and fifth reads were bad and all others were good.

5.4 READ PASS OUT OF SYNC

The first word of every record is the number of records preceding it on the tape. When each record is read, the program compares this first word with the read record count. If they disagree the program backspaces and rereads the record a second time, if they still disagree then the difference between them is computed and the program spaces over as many records as necessary to position itself in front of the correct record. If the first word of this record does not agree with the read record count after two attempts the program ends the read pass and outputs the following. As in a read error it outputs the read pass count, read record number, mode, density and unit number. This is followed by this message:

```
READ PASS ABORT, OUT OF SYNC.
aaaaaaa      bbbbbbb
```

where the a's represent the first word of the first record read that did not agree with the read record count, and the b's represent the first word of the record read after spacing to what should have been the correct record. The program then goes to the end of read pass section where the end of pass output will be produced and from there on to another write or reread pass.

If a tape mark or the load point was encountered when spacing, the program terminates the read pass and outputs TAPE MARK before the other outputs. If it was the load point which was encountered it also outputs LOAD POINT. In either case the two words a and b will be the same since only one record was read.

5.5 FILE PROTECT ON

Before the program attempts to write on a tape it tests the file protect for that unit. If the file protect should be on, the program outputs: FILE PROTECT ON (Mode) UNIT NO. n. and returns to the keyboard mode.

METHOD:

1.0 WRITING

At the start of the write pass all units are rewound. The program then sets the tape control table for the lowest numbered unit and waits for it to be ready. As soon as this unit is ready a check is made to see if the tape is at

METHOD: (cont.) the loadpoint. If it is not, another rewind is given and the program waits until it is ready and at the load point. A three inch section of tape is erased before the first random number record is written. After writing this record on the first unit the control table is set to the next higher numbered unit and the record is written again. This continues until a record has been written on all units under test. The program then generates a new record of random numbers and starts writing this on all units.

1.1 WRITE ERROR

If a write error occurs the program erases backward to the front of this record and attempts to rewrite it. If this second attempt is also in error then the program outputs the rewrite error message. It then erases backward over the record again, erases it forward and attempts to write the record again on a new section of tape. An error here is considered a new write error and the process continues until a correct write is made.

1.2 END OF PASS

The write pass is concluded if one of two conditions occurs: Either the write record count reaches the maximum record count or an end of reel is encountered on any tape under test. When one of these occurs the program writes an end of file on all units and rewinds them. It then outputs the end of pass message and proceeds to the read pass.

2.0 READING

A read pass is similar to a write except that the program reads each record into memory and compares it with the random numbers which it regenerates for each read. The first record must be read starting from the load point. This insures that the tape is always positioned properly for the start of the pass.

2.1 READ ERRORS

When a read error occurs the program will always reread the record nine more times for a total of ten attempts regardless of whether or not a subsequent read was correct. It then outputs the results of these reads. Several conditions can cause a read error.

2.1.1 Character Parity Errors

The program counts a character parity error as any buffer error which occurs before the gap is reached.

METHOD: (Cont)

2. 1. 2 Longitudinal Parity Error

If no character parity errors have occurred before the gap is reached and the buffer error is on after the tape stops, the program counts a longitudinal parity error.

2. 1. 3 Word Count Error

A word count error is defined as a record which was not of the length expected. The program tests for this in three ways. If more words than expected were read the read routine falls out of the loop too soon. The program also checks to see if the read loop should detect the end of record before expected. The third test is based on the fact that the program always writes records that consist of a multiple of four characters. Therefore, if the buffer contains anything other than zero at the end of the read an error has occurred.

2. 2 READ SYNCHRONIZATION

When each record is read the first word is compared against the program record count. If they disagree it means that the program and tape are no longer synchronized. To guard against a read error causing the disagreement, the program backspaces and reads the record again. If they still disagree then the program computes the number of records to be spaced over in order to reach the desired record and moves to that point. It reads the new record and again checks the first word. If this word disagrees with the record count and a second read attempt does not correct the disagreement then the program aborts the read pass and outputs the appropriate message. If a tape mark or the load point is encountered while spacing to the correct position the pass is aborted without further read attempts.

2. 3 END OF FILE

If the program should detect the buffer ready after the first word is read then a check for end of file is made. If the ready condition was caused by the reading of a tape mark then the read pass is complete and appropriate messages are output. If there is no tape mark character then the program assumes that the tape mark was read erroneously and terminates the read pass anyway and outputs an END OF FILE READ ERROR message.

METHOD: (Cont)

3.0 BCD MODE

In the BCD mode random numbers are generated and written the same as in binary. However, on the read pass all non compares between the generated number and the number from tape are checked to see if they are caused by the 12 to 00 conversion. This occurs because both the character 00 and the character 12 will be written on tape as a 12 but this character will always be read into memory as a 00.

IDENTIFICATION: Buffered Line Printer Memory Dump

AUTHOR: R. Wilborn, SDS

ACCEPTED: January 11, 1964

COMPUTER CONFIGURATION: Any SDS 910 or SDS 920 with an SDS Model 9173 buffered line printer.

PURPOSE: To provide a method of printing the contents of memory via the line printer.

PROGRAMMED OPERATORS: None.

STORAGE: 204 including output buffers.

TIMING: Will print at the maximum rate of the line printer.

USE:

1. The Line Printer Memory Dump Program is in relocatable format with a relocating loader. To load the program at Location L, enter L in the A register and follow the normal fill procedure.
2. After loading, the program will halt. The area to be dumped is defined by loading the A and B registers.

A = Starting Location

B = End Location
3. Following the dump, the paper in the printer is restored to the home position. Another dump may be initiated at this time.

METHOD: Data is printed 8 memory locations per line, 50 lines per page. The address of the first word is displayed at the left of each line. If the entire line is zero, a line of blanks will be printed.

SDS 900 SERIES PROGRAM LIBRARY

LISTING

IDENTIFICATION: Line Printer Test Program

AUTHOR: R. Wilborn, SDS

ACCEPTED: 19 June 1963

COMPUTER
CONFIGURATION: Any SDS 920 or SDS 910 with an SDS Model 9170 line printer.

PURPOSE: To provide an acceptance test for the SDS Model 9170 line printer.

PROGRAMMED
OPERATORS: None

STORAGE: Octal locations 200-3000 (1408 words)

TIMING: The printer is driven at its maximum rate:

300 lines per minute printing, or

120 lines per second while slewing.

USE: The Line Printer Test Program is on a self-loading paper tape.

1. Load the program by the normal Fill procedure. When the program is loaded, the computer will halt.
2. The paper should be adjusted in the printer such that the perforation between sheets is directly over the hammers. After the initial setting, the program will maintain form control and the page will be restored after each test.
3. Select the functions to be tested before clearing the halt.
 - BP 1 Set: No action.
 - Reset: Each character is printed in every print position (Figure 1).
 - BP 2 Set: No action.
 - Reset: Tab and backspace features are utilized (Figure 2).

USE: (cont.)

BP 3 Set: No action.

Reset: Slew 1 page (Figure 3).

BP 4 Set: No action.

Reset: Vertical and horizontal control are checked by printing a checkerboard of E's (Figure 4).

Testing will continue as long as the particular test is called for by the breakpoints being reset. If all the breakpoints are set the program will loop until a test is called for.

METHOD:

Not applicable.

- * THE FOLLOWING TEST WILL PRINT A GROUP OF LINES WITH AND WITHOUT TAB/BACKSPACE CONTROL. AFTER THE FIRST GROUP HAS BEEN
- * PRINTED A HALT WILL OCCUR AND THE POSITION OF THE CONSOLE TAB/BACKSPACE SWITCH SHOULD BE REVERSED. THEN CLEAR THE HALT

THIS IS A TEST OF THE TAB AND BACKSPACE FEATURE OF THE SDS LINE PRINTER.

SDS 900 SERIES PROGRAM LIBRARY

PROGRAM DESCRIPTION

Page 1 of 2

Catalog No. 064002B

IDENTIFICATION: Buffered Line Printer Test Program

AUTHOR: M. R. Mulholland, SDS

ACCEPTED: 22 May 1964

COMPUTER
CONFIGURATION: Any SDS 910 or SDS 920 computer with an SDS
buffered line printer.

PROGRAMMED
OPERATORS: None

STORAGE: Locations 100_g and 150_g-2336_g (1144 locations).

TIMING: The printer is driven at both its normal rate (300
lines per minute) and its maximum rate (1080 lines
per minute, or 120 lines per second, while slewing).

USE: The Buffered Line Printer Test Program is on a
self-loading paper tape.

1. Load the program by the normal FILL procedure. When the program is loaded, the computer will halt.
2. The paper should be adjusted in the printer such that the perforation between sheets is directly over the hammers. After the initial setting, the program will maintain form control and the page will be restored after each test.
3. Select the functions to be tested before clearing the halt.

BP 1 Reset: No action.
Set: Each character is printed in
every print position (Figure 1)

BP 2 Reset: No action.
Set: Vertical format channels and
vertical spacing is tested
(Figure 2)

USE: (Cont)

- BP 3 Reset: No action.
 Set: Vertical and horizontal control are checked by printing a checkerboard of E's (Figure 3).
- BP 4 Reset: No action.
 Set: Maximum speed is attained in printing by printing the same character in the left most 64 character positions on a line, with each successive line printing the character which lies at an interval of approximately one-third of the distance around the printing drum from the preceding character (Figure 4).

Testing will continue as long as the particular test is called for by the breakpoints being set. If all the breakpoints are reset, the program will loop until a test is called for. If the breakpoints are all reset (upon completion of any test), the printer will slew the paper to the top of the next page.

METHOD:

Not applicable.

IDENTIFICATION: 42 KC Magnetic Tape Test

AUTHOR: A. W. England, SDS

ACCEPTED: 13 May 1963

COMPUTER
CONFIGURATION: All SDS 920 systems and any 910 with a typewriter which have one or more magnetic tape units connected to the W buffer.

PURPOSE: To provide a simple and easy means for initial checkout and testing of 42 KC magnetic tape units.

PROGRAMMED
OPERATORS: None.

STORAGE: The program occupies 587 words from 400g to 1512g. It uses the HELP Word Output Subroutine located at 200g. The area from the end of the program to the end of memory may be used as input and interlaced output record image.

TIMING: The program is sufficiently fast to keep the tape operating at full speed for all operations.

USE: 1.0 LOADING

To load the program, insert the paper tape in the paper tape reader and follow the normal FILL procedure. When it is loaded, the light on the typewriter will indicate that the program is now under operator control.

1.1 REGAINING OPERATOR CONTROL

If at anytime the operator should lose control of the program he may return it to the keyboard mode by moving the RUN-IDLE-STEP switch to IDLE, pressing START, moving the switch to STEP and then to RUN. If for some reason location 0001 is destroyed he may execute a BRU to location 400 to return control to the keyboard.

2.0 CONTROL FUNCTIONS

The following list contains a call letter for the various control functions the program will perform. These may be typed anytime the light on the typewriter is lit.

USE: (cont.) 2.1 PARAMETER CONTROL

These functions cause the program to set up the various parameters for the tests which will follow.

2.1.1 P, Set Pattern

The previously typed 8 octal digits are set up as the pattern for writing operations.

2.1.2 L, Set Record Length

The previously typed octal number will be established as the record length for all subsequent test operations. For write operations it determines the number of words to be written. For read it determines the maximum number of words which will be stored in memory. The maximum length record is 7777₈ (4095). If a larger number is entered it will be reduced to this maximum.

2.1.3 U, Set Unit Number

The previously typed octal digit is used to identify the logical tape unit number which is to be tested. The program adjusts all tape unit addressing instructions accordingly.

2.1.4 C, Set Record Count

The record counter is incremented by one every time the program passes a record in the forward direction, and decremented by one for the reverse direction. After a rewind it is cleared to zero. This control function with the letter C is provided so that the user can reset this counter whenever he wishes to start a series of operations for which a count is needed. The previously typed 8 octal digits will be saved as the new record count.

2.1.5 Z, Set Parity

If the preceding digit is even the program converts all read and write EOM's to the BCD even parity mode. If the digit is odd it converts all read and write EOM's to the binary odd parity mode.

2.2 TAPE OPERATION CONTROL

2.2.1 Breakpoint Functions

Breakpoints 1, 2 and 4 apply generally to all tape operations. Breakpoint 3 is used when writing.

USE: (cont.)

BP 1 RESET: Continuous operation. The operation will continue as long as this Breakpoint is RESET or until the end of tape is reached.

SET: Stop continuous operation. If initially SET do only one operation.

BP 2 RESET: Perform all operations without stopping between records.

SET: Stop after each record.

BP 3 RESET: Write normally.

SET: Write a continuous record as long as this Breakpoint is set.

BP 4 RESET: Stop if a read or write error occurs.

SET: Do not stop on a read or write error.

2. 2. 2 W, Write

The previously set pattern will be written as a record of length indicated by the L function. Records will be continuously written as long as Breakpoint 1 is RESET. If Breakpoint 3 is SET one long continuous record will be written. If Breakpoint 4 is RESET and a write error occurs, the program will halt and print WRITE ERROR. If Breakpoint 4 is SET the error will not cause a stop. If the tape is situated on the end of tape marker the write routine will write a Tape Mark to signify end of file, then type END OF REEL, and return to keyboard.

2. 2. 3 I, Write with Identification

This function is the same as Write except that the record count number is written as the first word of the record. This provides a unique identification word for each record. The record count word is inserted as the first word of the image so no additional words are added to the record.

2. 2. 4 R, Read

The next record on the selected tape unit will be read into memory. If the record is longer than the preset record length, the program will skip the extra words. If the skip remainder of record operation is not functioning and additional I1 interrupts occur, the program will count these and print the count at the end

USE: (cont.)

of the record. As long as Breakpoint 1 is RESET the program will read records sequentially until an end of file or the end of tape is encountered. If Breakpoint 2 is SET, the program will stop the tape after each record; otherwise the tape will run without stopping.

If a read error occurs and Breakpoint 4 is RESET, the program will stop and type READ ERROR. If BP 4 is SET, the program continues.

2. 2. 5 B, Backspace

If the input number previous to the B is cleared to zero by a carriage return then the selected tape is backspaced one record at a time as long as Breakpoint 1 is RESET or until the load point or an end of file is encountered. If the input number previous to the B is non zero then it is decremented by one after each backspaced record and the backspacing operation is terminated when it reached zero. The counted backspace may also be stopped on Breakpoint 1, the load point, or an end of file. If Breakpoint 2 is reset, the spacing will proceed without stopping between records. If Breakpoint 2 is set, the tape will be stopped after each record spaced and then restarted to continue over the next one.

2. 2. 6 S, Space Forward

Space forward is the same as backspace except that it will also stop when the end of tape is reached.

2. 2. 7 X, Search-Forward

The selected tape is searched forward using the read-scan mode until a record is found whose first word is equal to the previously typed octal number. When the record is found it is read into memory. If an end of file or the end of tape is encountered before the record is found the tape is stopped.

2. 2. 8 Y, Search Reverse

The selected tape is scanned backward until a record is found whose first word (last word scanned over in reverse) is equal to the previously typed octal number. If an end of file or the load point is encountered before the record is found, the tape is stopped.

2. 2. 9 D, Rewind

The selected tape is started in a rewind and the program returns to keyboard control.

USE: (cont.)

2.2.10 E, Erase

This function is similar to write except that instead of writing information, it erases tape for a distance equal to the specified record length.

2.2.11 F, Write End of File

A tape mark is written on tape to indicate End of File. The record counter is not incremented by the operation. The operation may be executed even though the tape is on the end of tape conductive leader.

2.3 OUTPUT CONTROL

After the tape has been read or moved by some other operation, the results may be inspected using the following control characters.

2.3.1 N, Tape Record Count Number

The program will type the current contents of the record counter.

2.3.2 T, Type Record Read

If the number of words read was less than or equal to the preset length, the program will type: RECORD LENGTH < OR = LLLL, where LLLL represents the record length. If the number of words read exceeds the present record length, the program will type: RECORD LENGTH > LLLL.

After typing one of these messages the program will begin to type the record image in octal numbering each eighth word in octal. This output will continue until either Breakpoint 1 is SET or until the entire record is typed.

If Breakpoint 1 is SET when the T key is struck only the record length will be typed.

3.0 STATUS AND ERROR MESSAGES

The following messages will be typed by the program to inform the operator of the status of the tape operation:

USE: (cont.) 3.1 WRITE ERROR

This indicates that the program detected a write error and Breakpoint 4 was RESET. The tape is stopped and the program returns to keyboard control after typing.

3.2 READ ERROR

This indicates that the program detected a read error and Breakpoint 4 was RESET. The tape is stopped and the program returns to keyboard control after typing.

3.3 SKIP REMAINDER OF RECORD ERRORS: nnnnnnnn

This indicates that the record read was longer than the preset record length and that when the program attempted to ignore the remainder of the record, it still received I1 interrupts. The number of interrupts is indicated by the octal number nnnnnnnn. Control returns to the keyboard after typing. This error stop may not be disabled by Breakpoint 4.

3.4 FILE PROTECT ON

This is typed whenever the user asks for a write or erase operation on a tape which has the file protect ring removed. After typing the program returns to keyboard control.

3.5 END OF REEL

This indicates that a forward operation has reached the end of tape.

3.6 LOAD POINT

This indicates that a reverse operation has reached the beginning of tape.

3.7 TAPE MARK

This indicates that a read, scan, or space operation has encountered an End of File record as indicated by the reading of a Tape Mark.

4.0 FUNCTION SUMMARY

In the calling sequence the small letter d is used to denote an octal digit.

USE: (cont.) 4. FUNCTION SUMMARY (cont.)Function Description

| | |
|------------------------------|-----------------|
| Clear digit accumulator | Carriage Return |
| Set test pattern word | dddddddP |
| Set record length | dddL |
| Set logical tape unit number | dU |
| Set record count number | dddddddC |
| Set to even parity (BCD) | ØZ |
| Set to odd parity (Binary) | 1Z |
| Write | W |
| Write with record count ID | I |
| Read | R |
| Backspace | B |
| Backspace by count | (octal count) B |
| Space forward | S |
| Space forward by count | (octal count) S |
| Search forward and read | dddddddX |
| Search reverse | dddddddY |
| Rewind | D |
| Erase | E |
| Write end of file | F |
| Type record count number | N |
| Type record read | T |

OMIT

METHOD:

Each functional routine is essentially independent of the others and attempts to accomplish its operation in as straight forward a manner as possible. The program attempts to prevent the tape from running off the reels in either direction. By using the write end of file operation, sections of the tape can be set off for further test without having to work from the beginning of the reel on every pass.

At the start of every routine, the status of the tape is tested and if the operation obviously cannot be accomplished the program does not attempt it. No reverse operation will be started if the tape is at the load point. No forward operation except write end of file will be started if the tape is on the end of reel marker. No write operation is attempted if the file protect is on.

All reading, spacing and searching operations will be unconditionally terminated when an end of file is encountered.

FLOW DIAGRAM

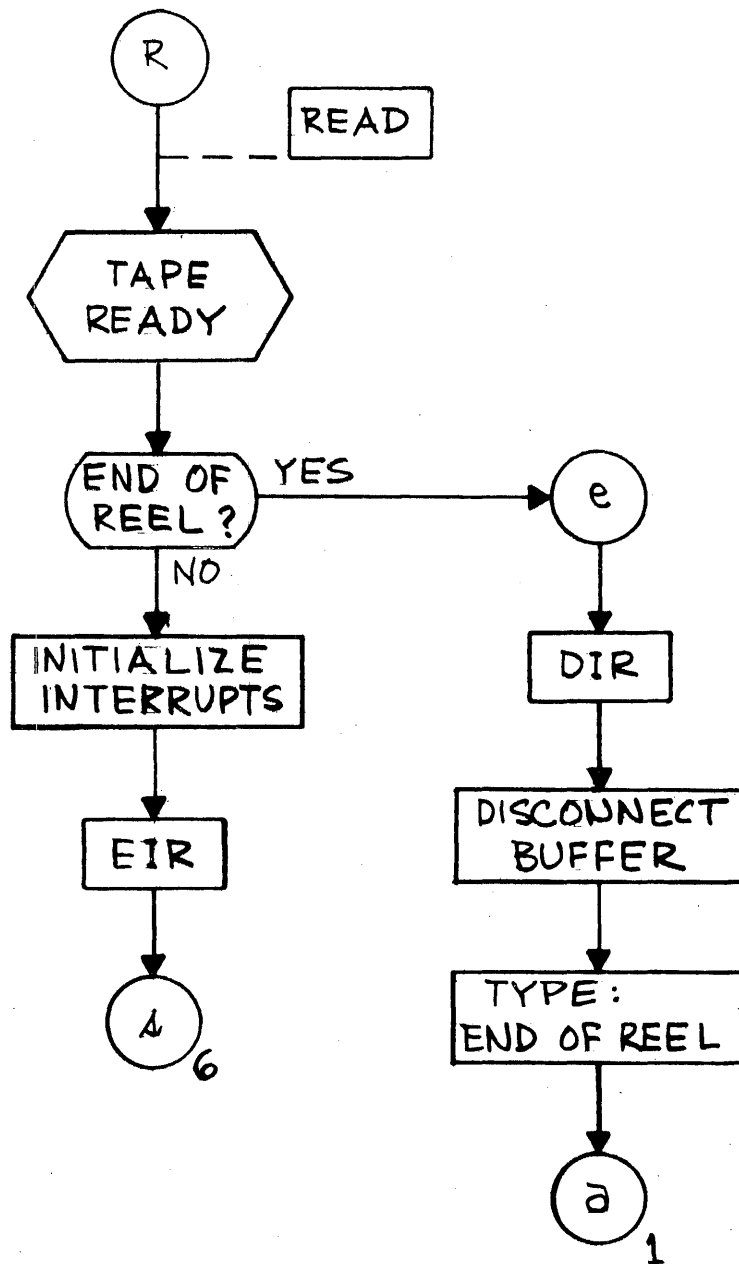

42 KC Magnetic Tape Test Program

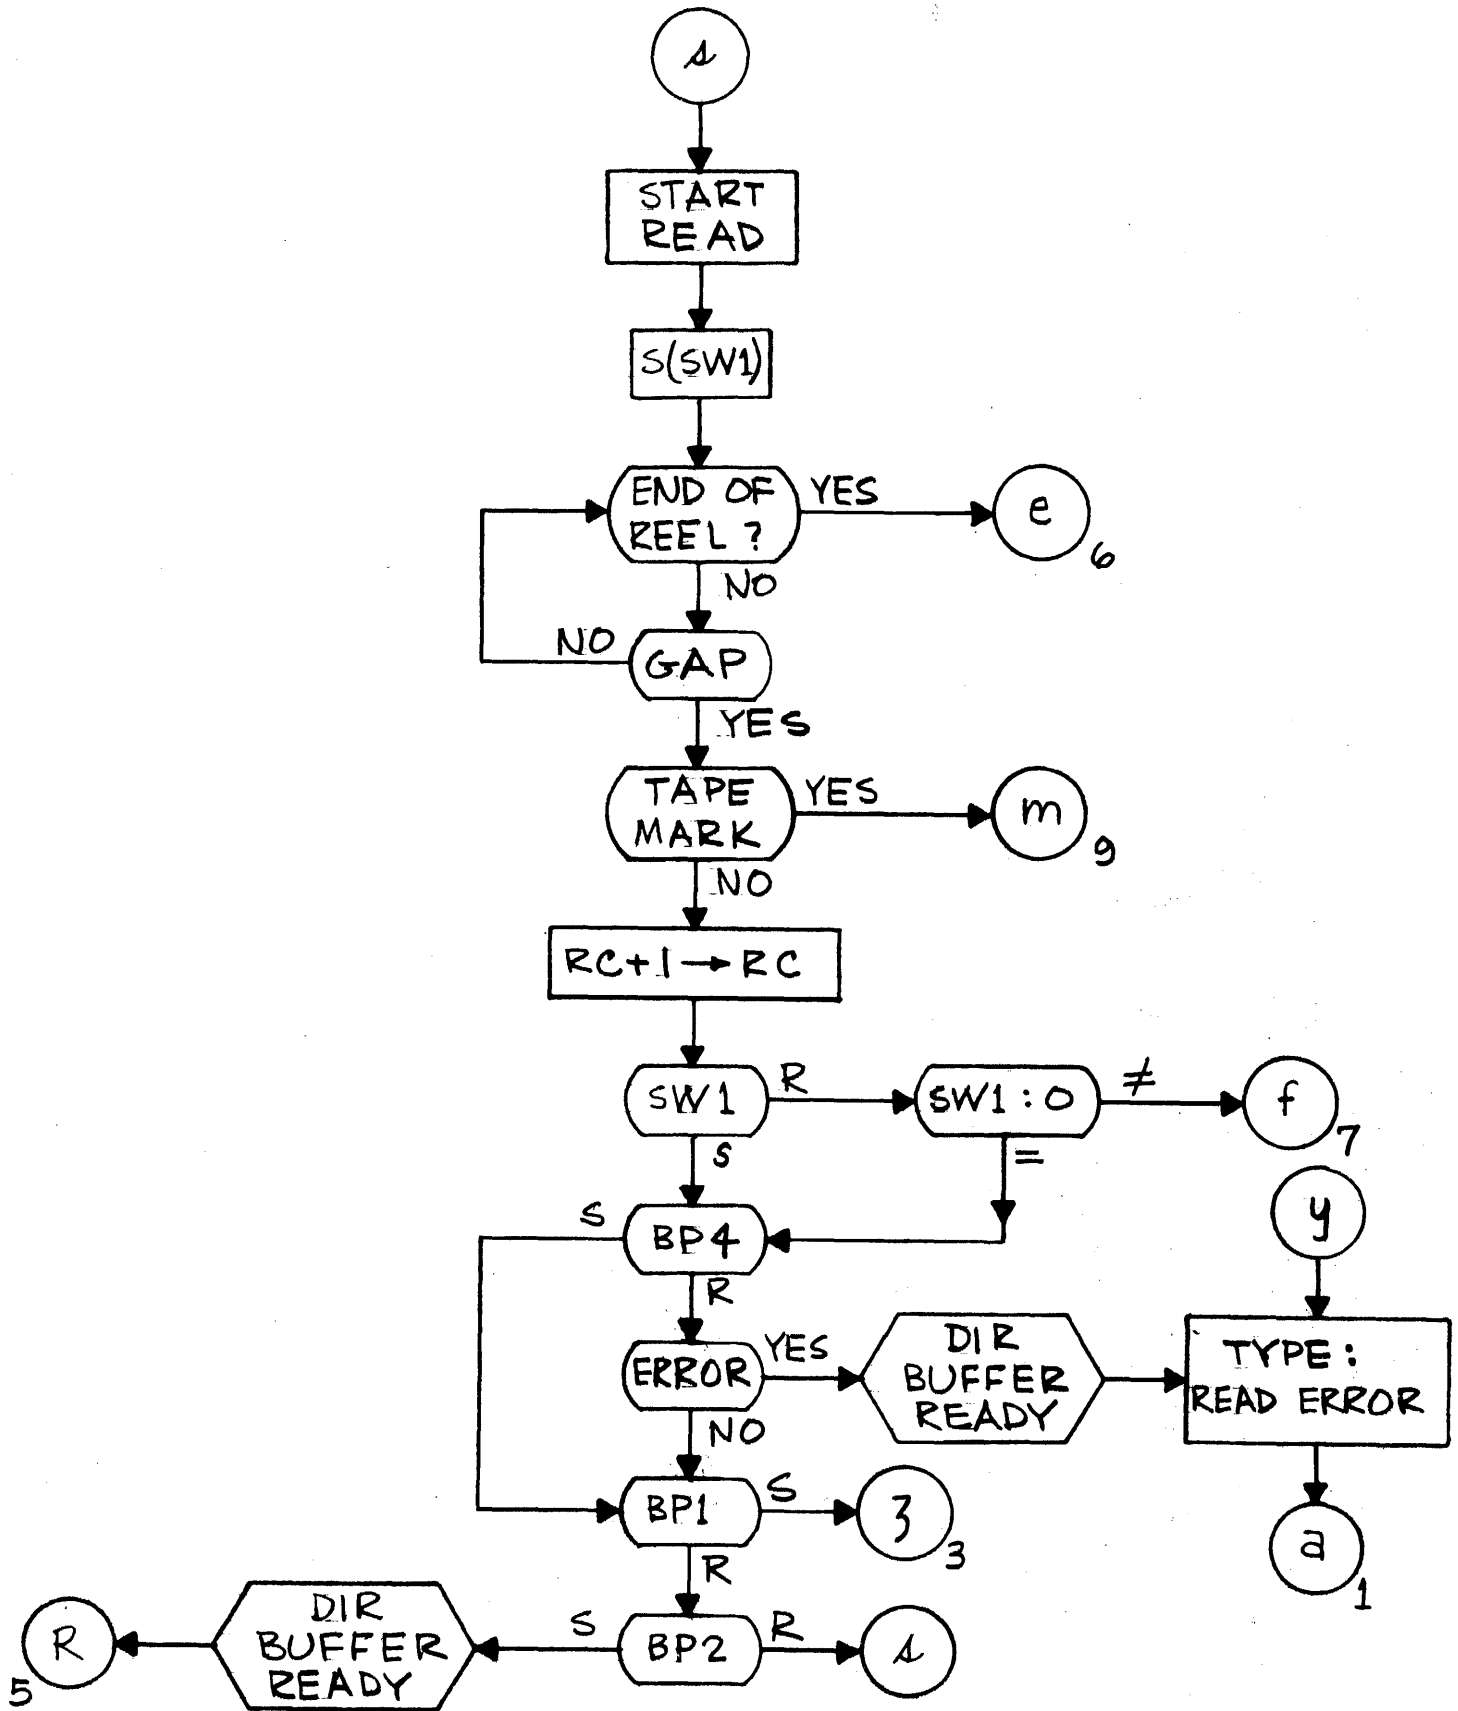

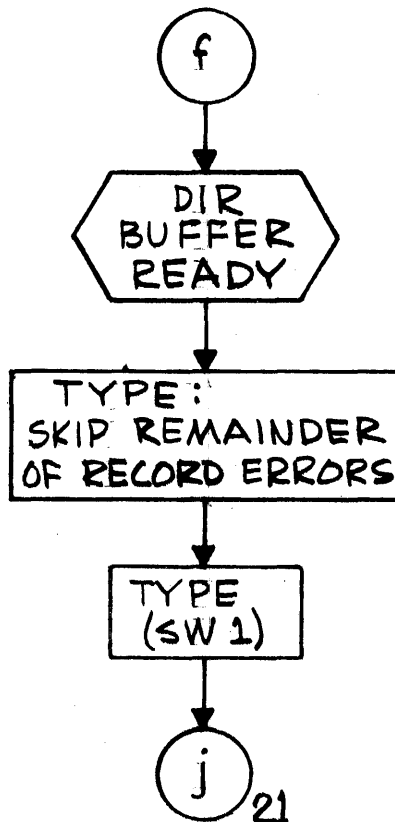

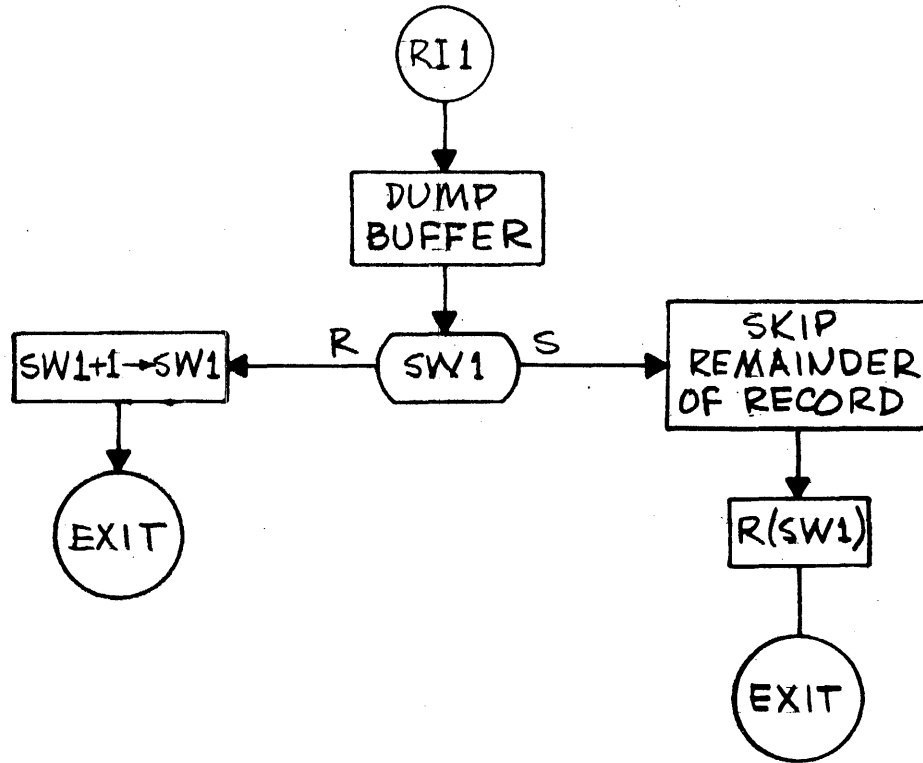

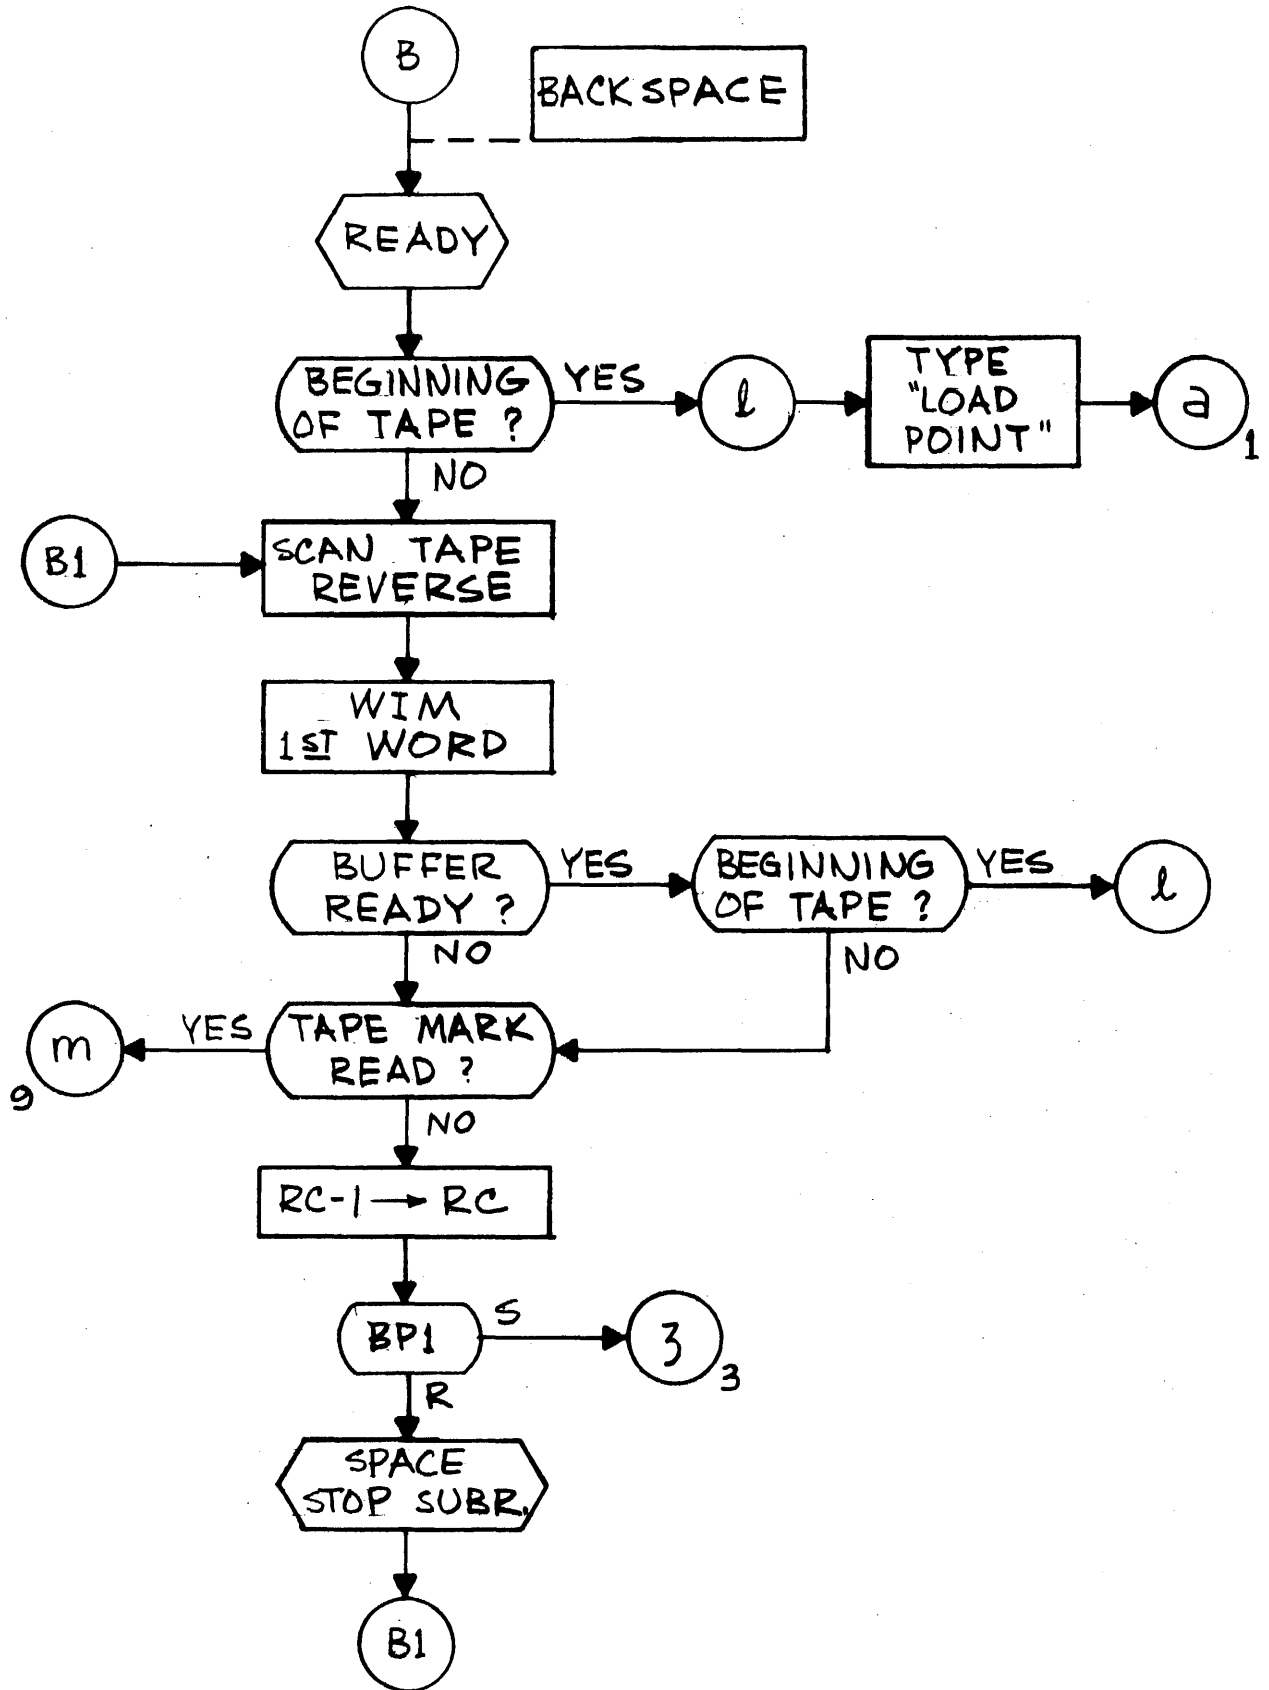

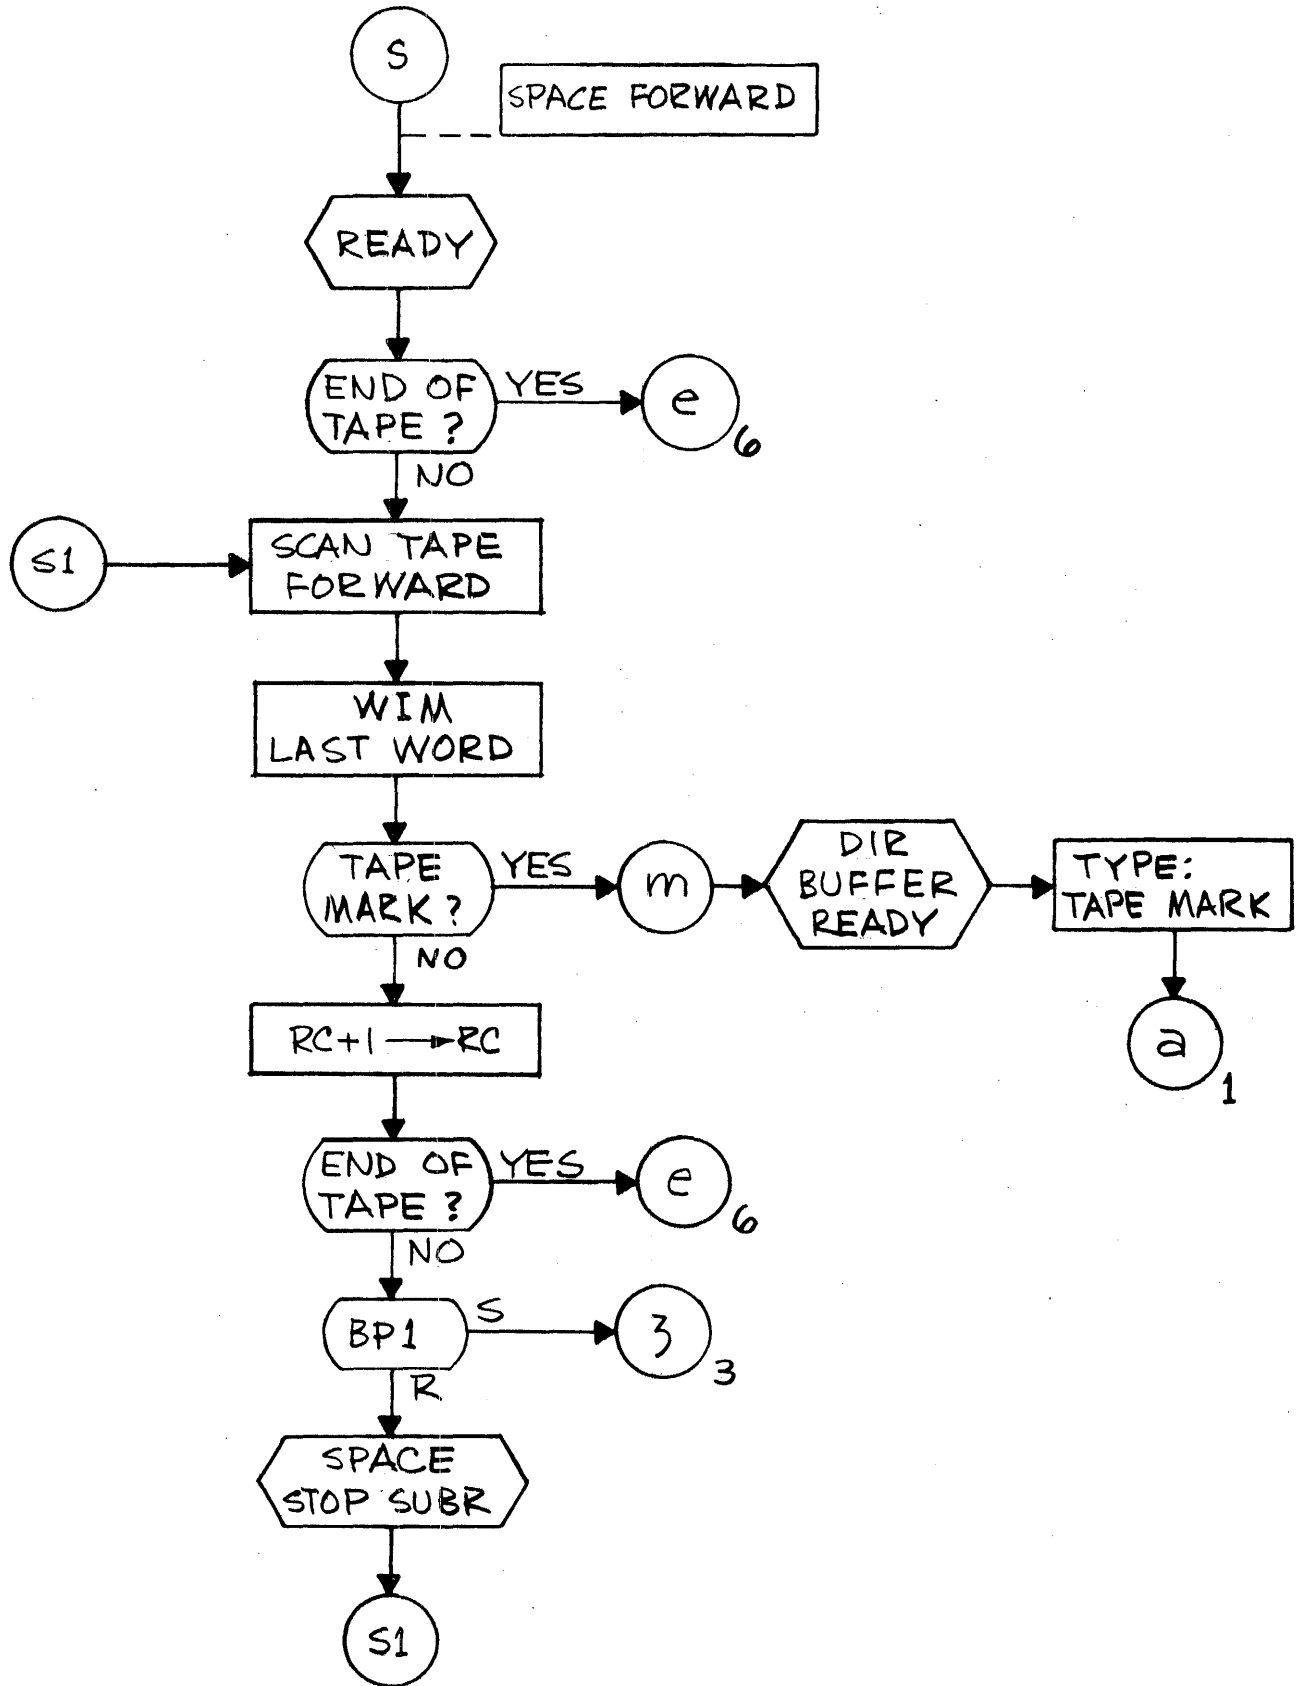

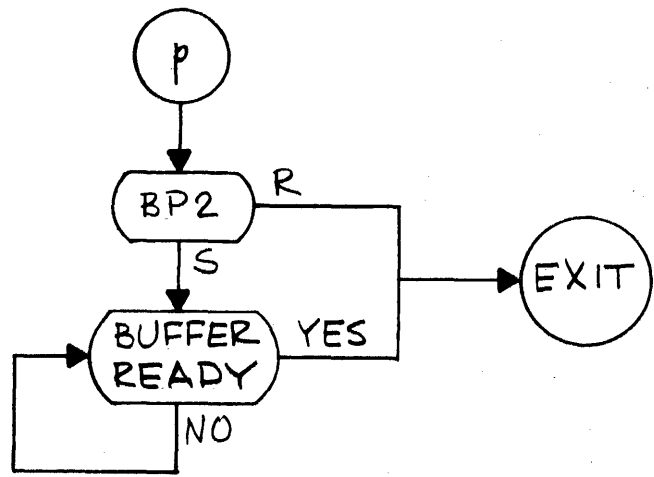

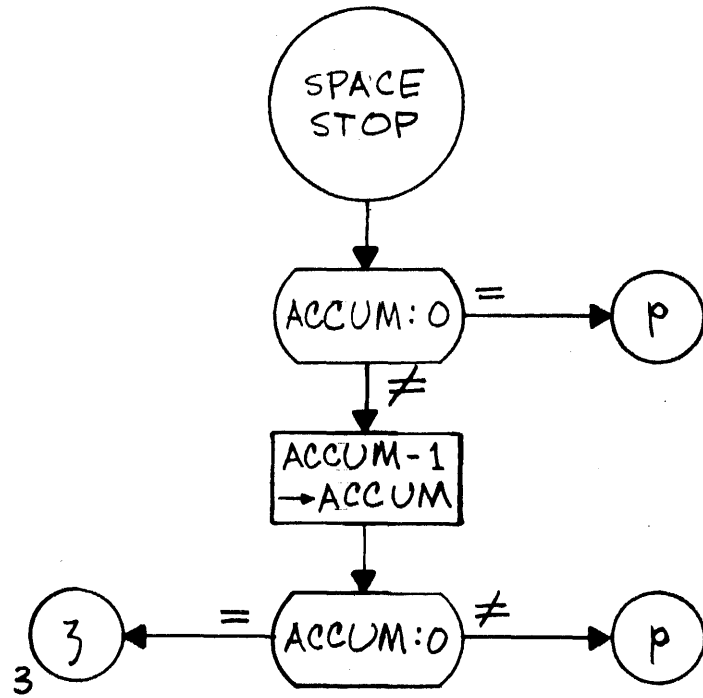

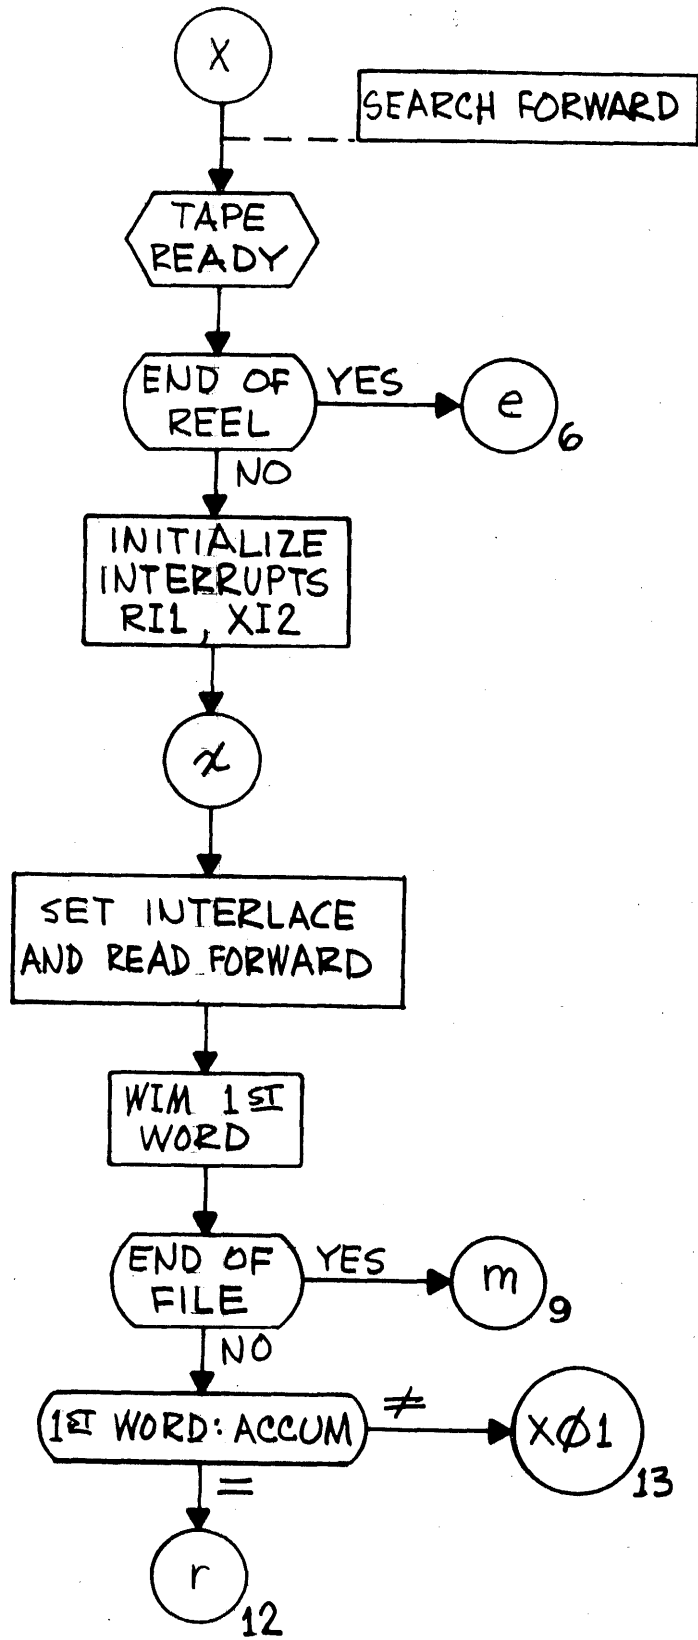

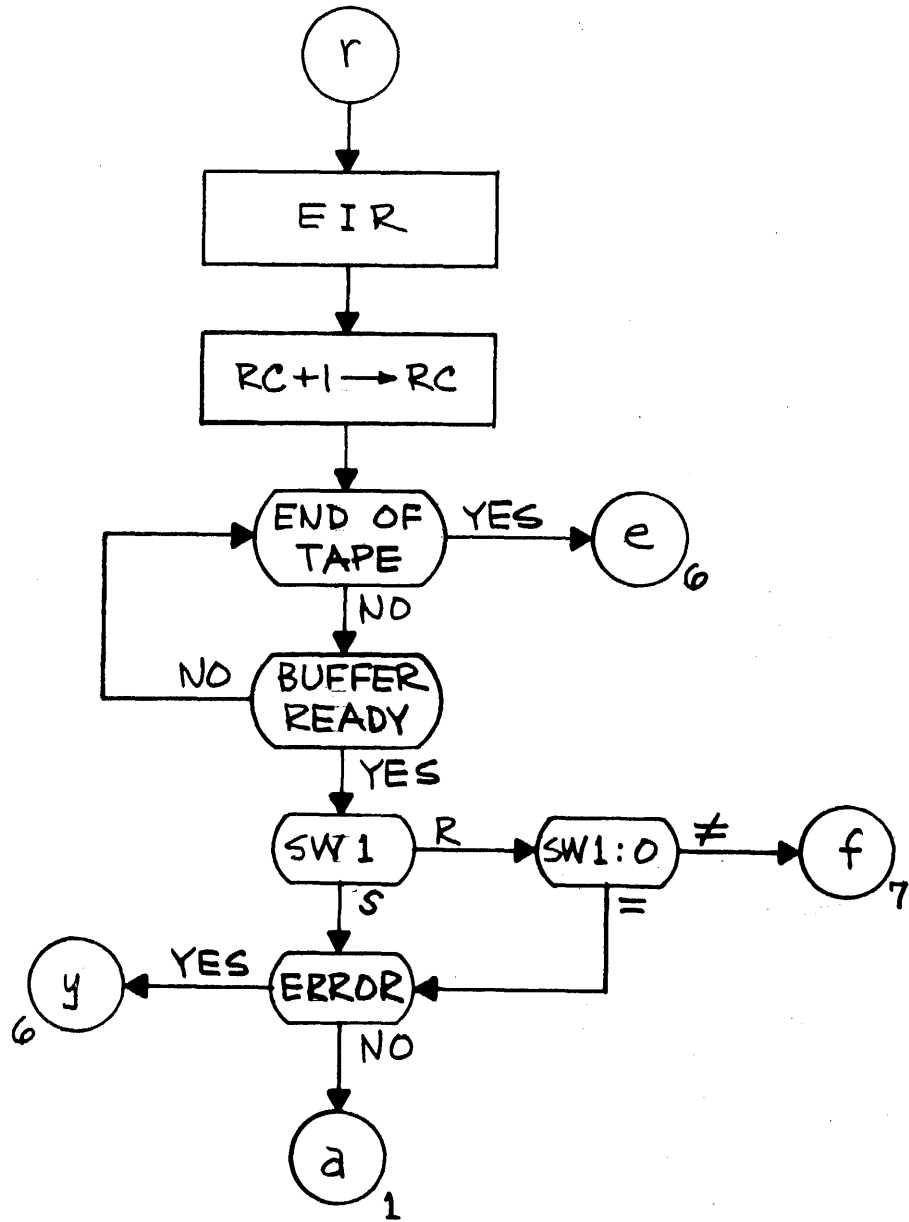

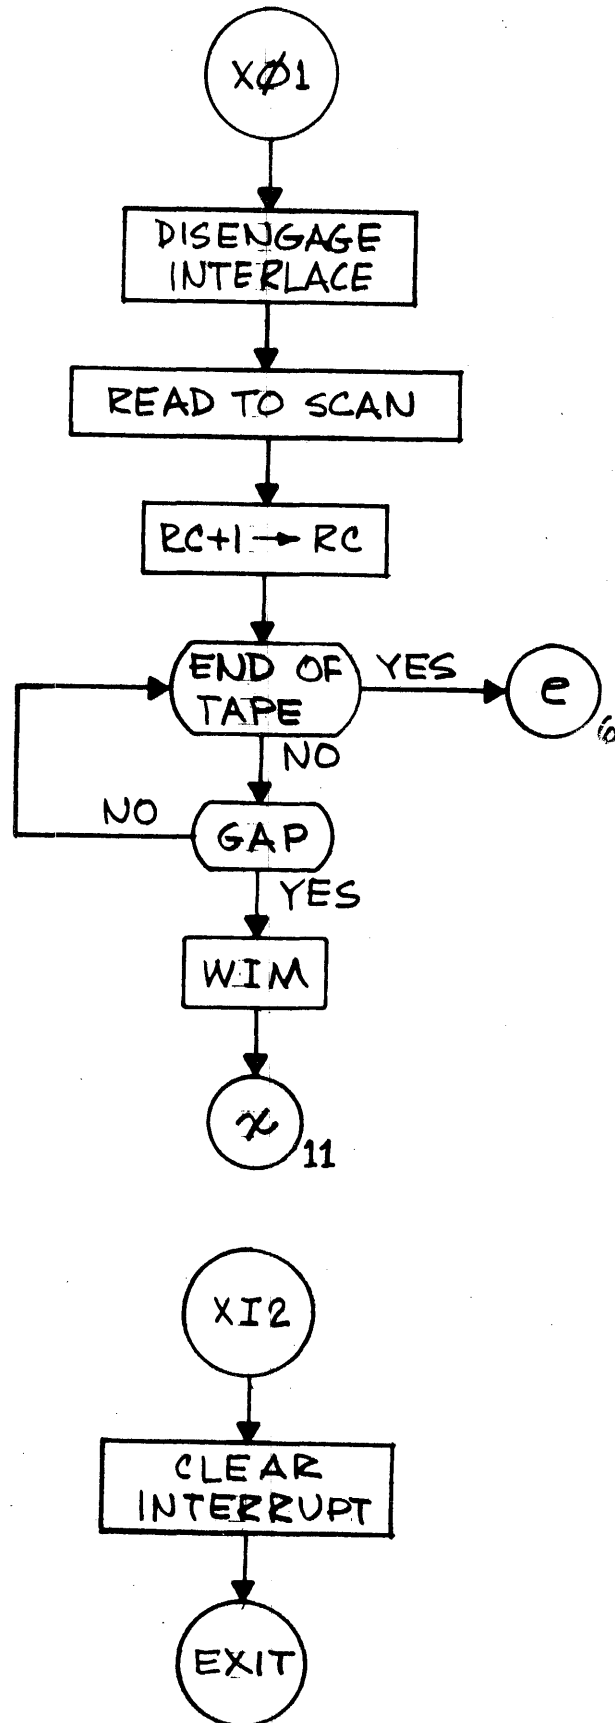

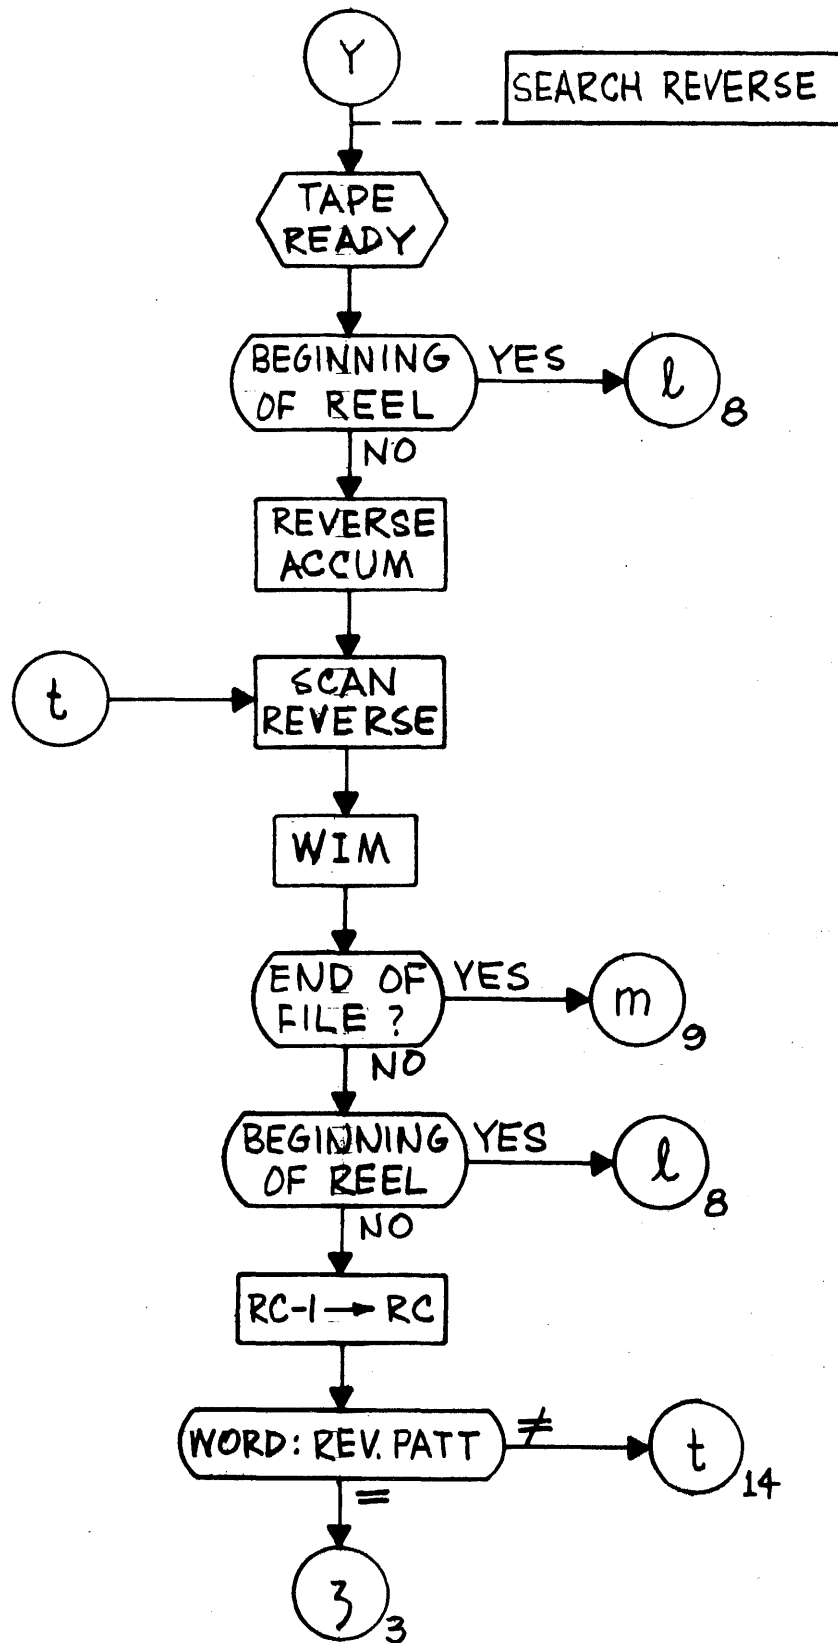

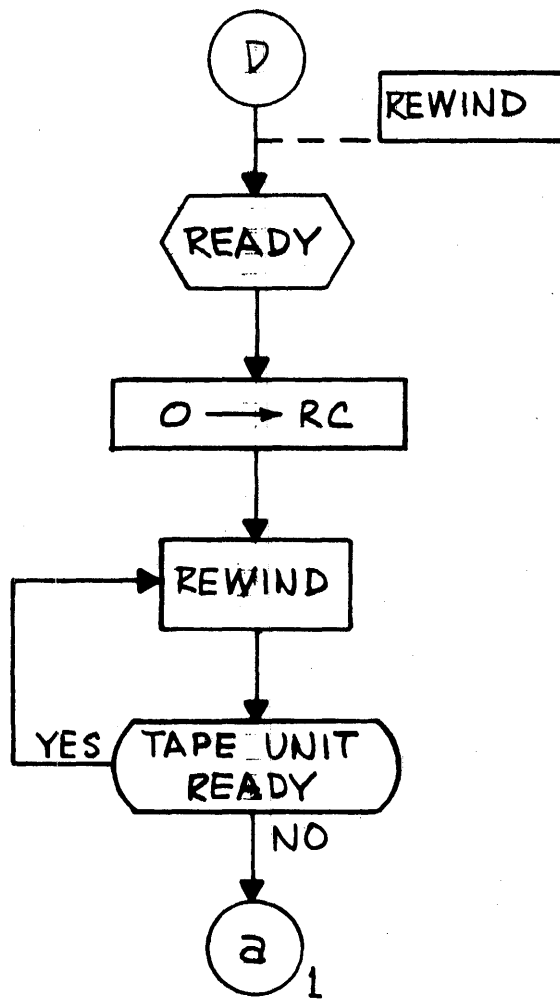

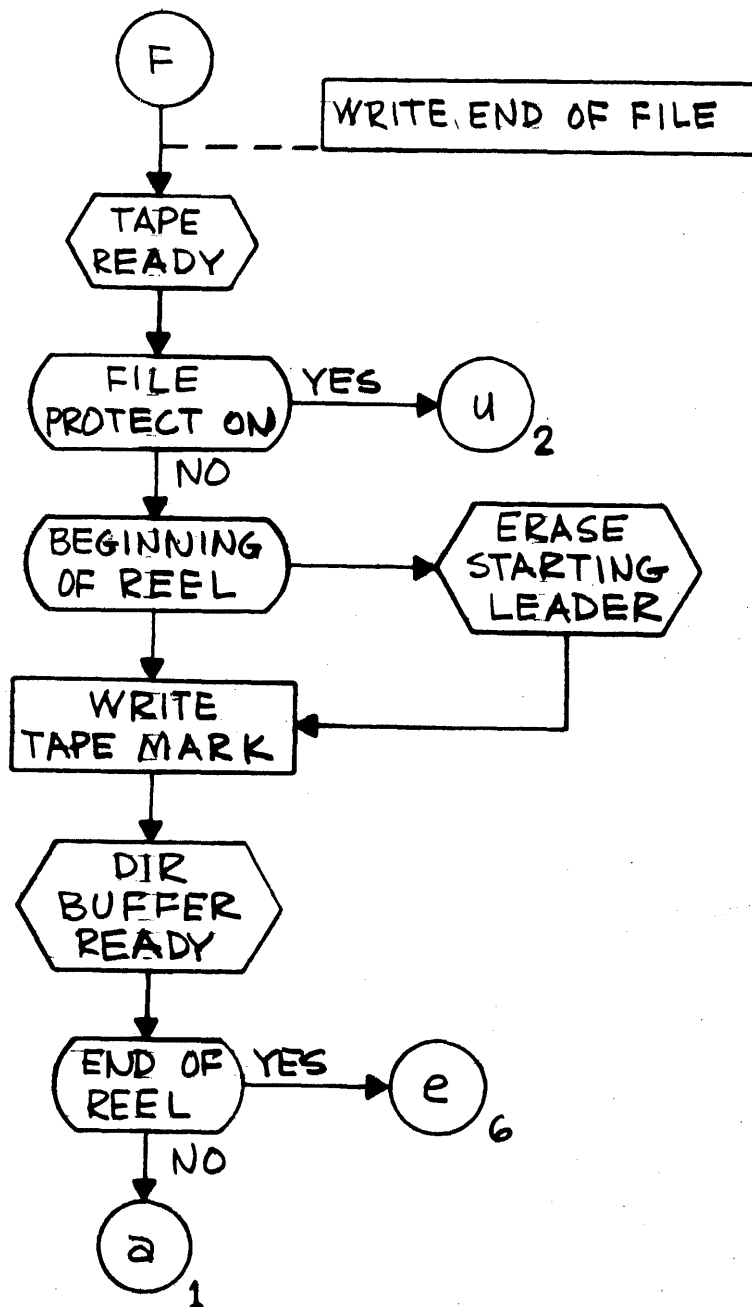

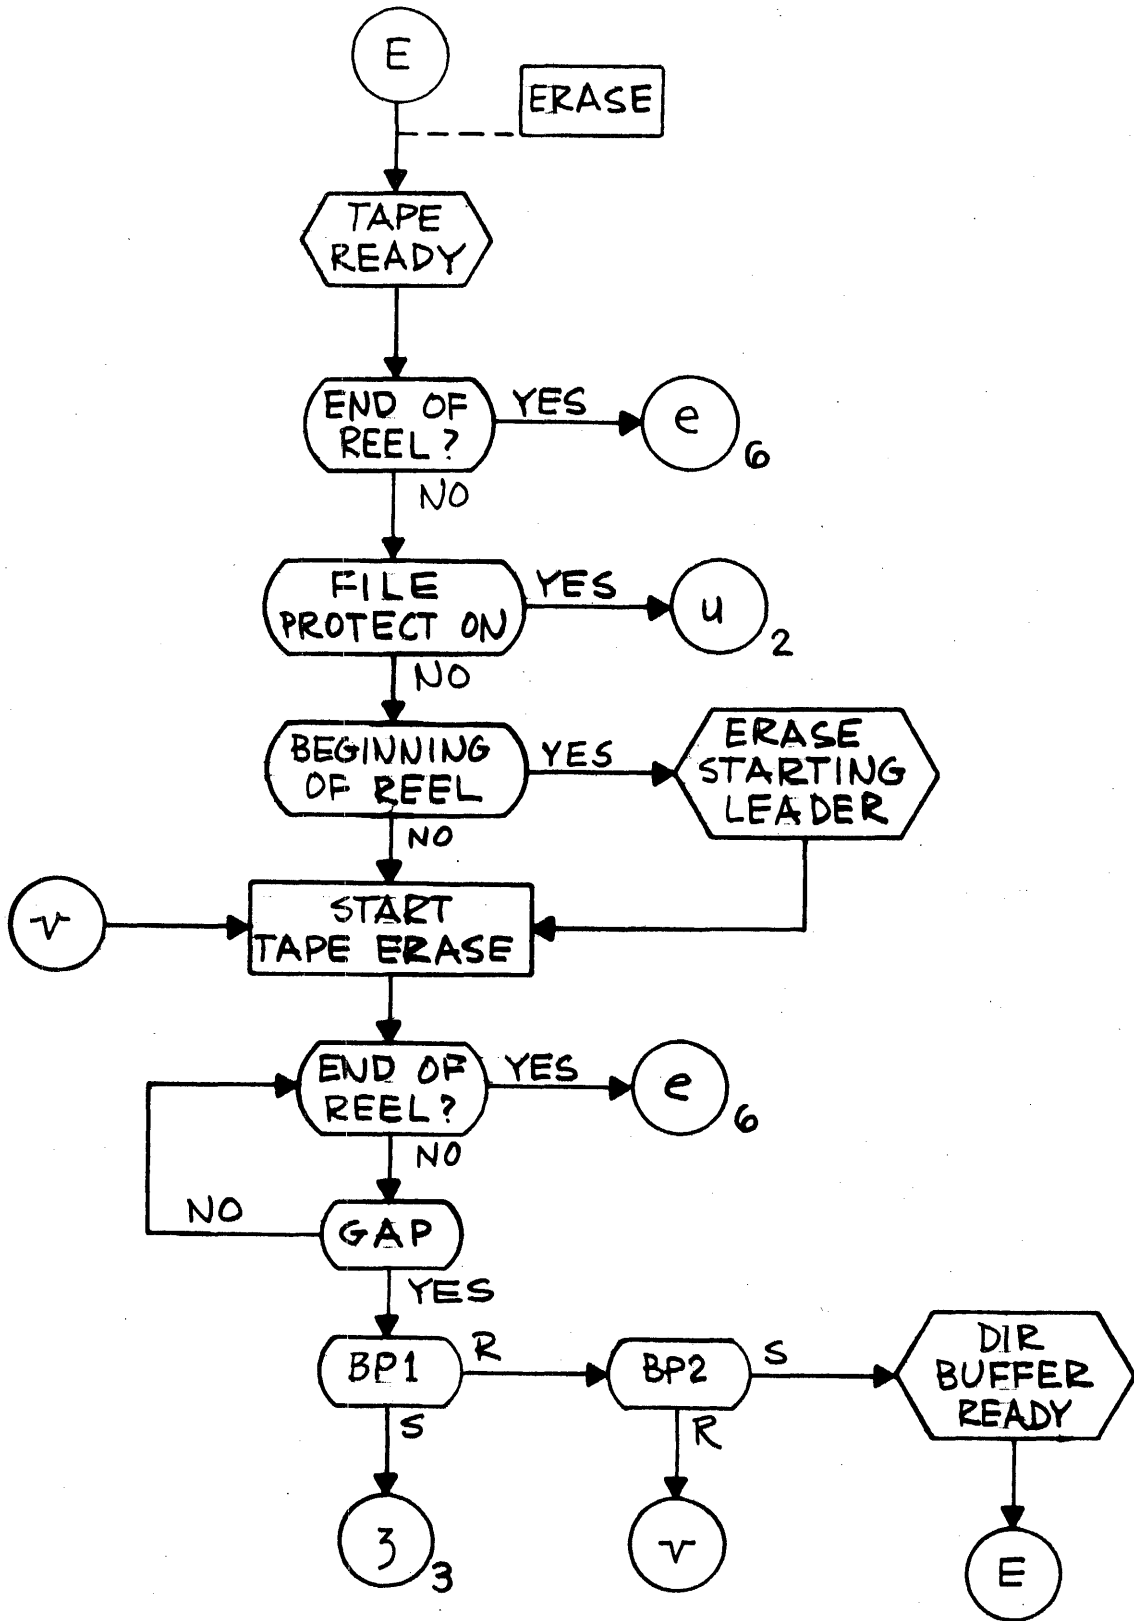

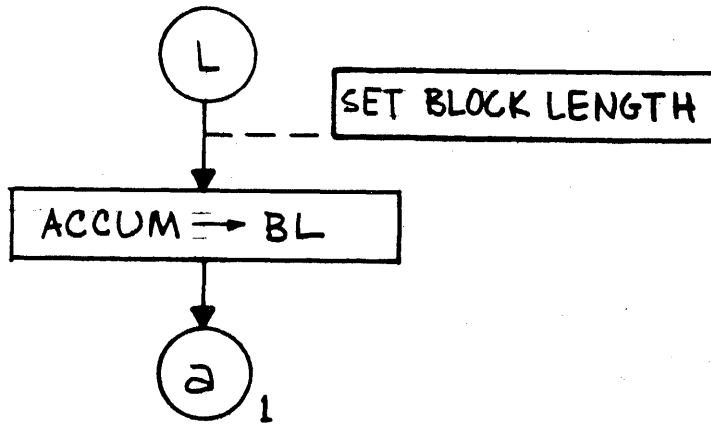

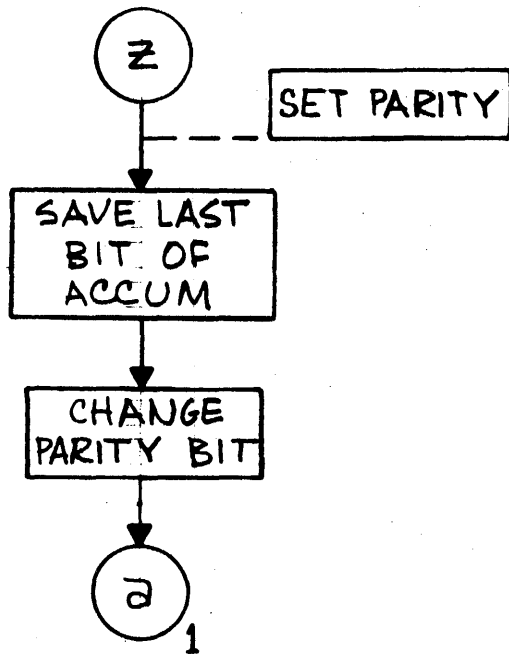

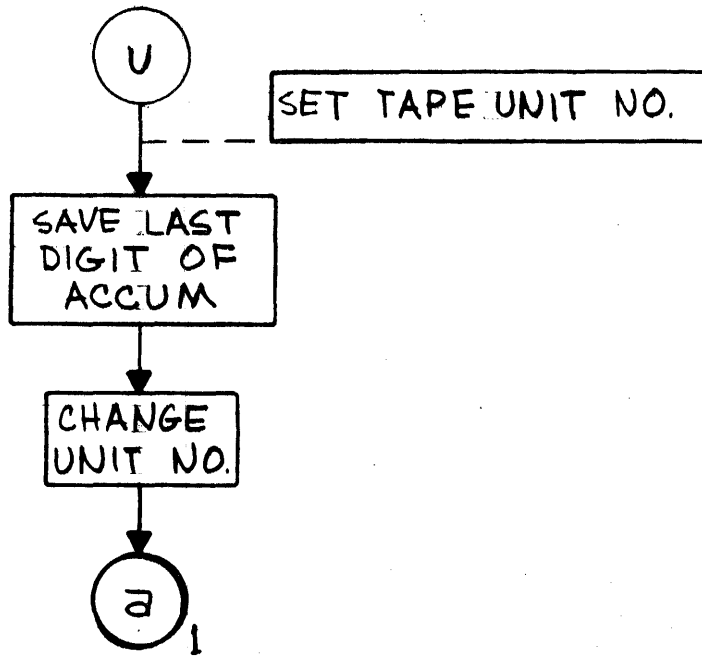

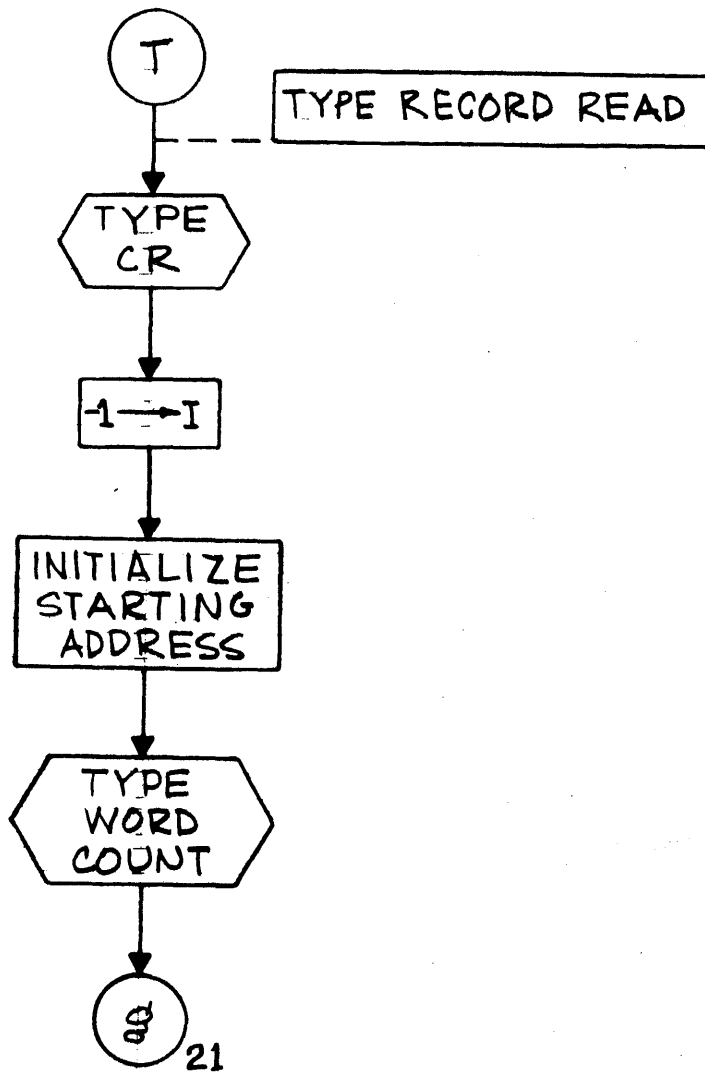

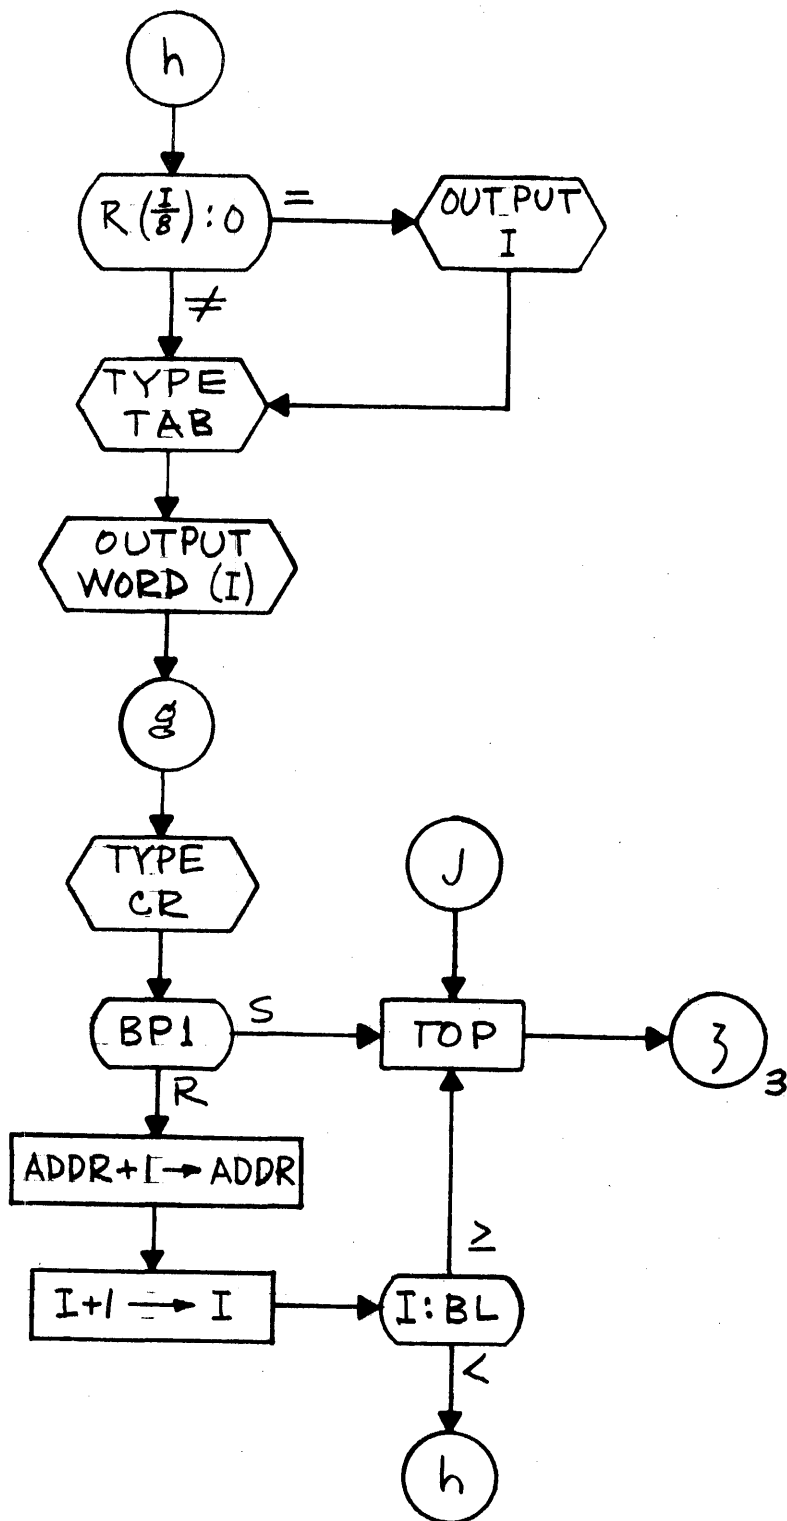

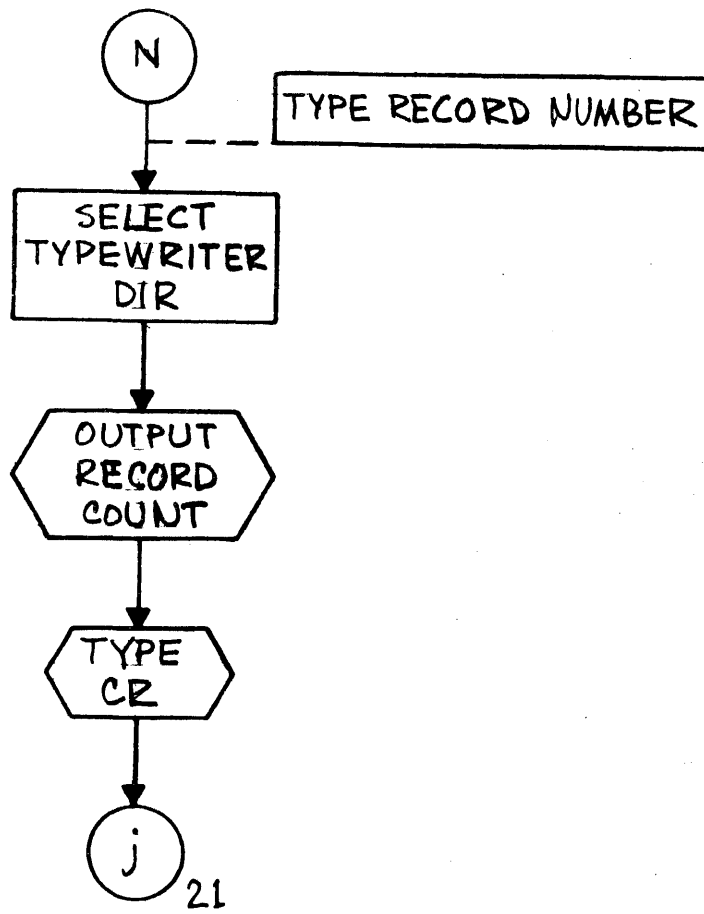

SDS 900 SERIES PROGRAM LIBRARY

PROGRAM DESCRIPTION

Page 1 of 1

Catalog No. 074002

IDENTIFICATION: 42 KC Magnetic Tape Test Program, Y Buffer

AUTHOR: A. W. England, SDS

ACCEPTED: 28 May 1963

COMPUTER
CONFIGURATION: All SDS 920 systems (or 910 with a typewriter) which have one or more magnetic tape units connected to the Y buffer through a 9248 tape control unit. The Y buffer must have a 9121 interlace control attached.

PURPOSE: To provide a simple and easy means for initial checkout and testing of 42 KC magnetic tape units.

PROGRAMMED
OPERATORS: None

STORAGE: The program occupies 593 words from 400g to 1520g. It uses the HELP Word Output Subroutine located at 200g. The area from the end of the program to the end of memory may be used as input and output record image.

TIMING: The program is sufficiently fast to keep the tape operating at full speed for all operations.

USE: The user is referred to the description of the W buffer version of this program (Catalog No. 074001) for details on USE and METHOD.

SDS 900 SERIES PROGRAM LIBRARY

PROGRAM DESCRIPTION

Page 1 of 1

Catalog No. 074003

IDENTIFICATION: 42 KC Magnetic Tape System Exerciser

AUTHOR: A. W. England, SDS

ACCEPTED: 28 May 1963

COMPUTER
CONFIGURATION: All 920 systems (or 910 with typewriter) which have one or more tape units attached to the W buffer through a 9248 tape control unit. The W buffer must have a 9121 interlace control attached.

PURPOSE: This program is designed to exercise from one to eight tape units by first writing random numbers in random length records on all tapes under test and then reading these records back and comparing them with the numbers written. An attempt is made to tabulate and output all useful information concerning the errors made, if any, the mode of operation of each unit, and the number of passes over the tape.

PROGRAMMED
OPERATORS: None

STORAGE: The program occupies from location 40g to 1776g. In a 2K machine the next 1023 words are used as a record buffer area. If the computer has a 4K memory the next 2047 words are used. If the memory is 6K or larger the next 4095 words are used.

TIMING: The program requires approximately 20 minutes to write or read a full reel (2400 feet) of tape.

USE: The user is referred to the description of the Y buffer version of this program (Catalog No. 074004) for details on USE and METHOD.

IDENTIFICATION: 42 KC Magnetic Tape System Exerciser, Y Buffer

AUTHOR: A. W. England, SDS

ACCEPTED: 23 May 1963

COMPUTER CONFIGURATION: All 920 systems, or any 910 with typewriter, which have one or more tape units attached to the Y Buffer through a 9248 tape control unit. The Y Buffer must have a 9121 Interlace control attached.

PURPOSE: This program is designed to exercise from one to eight tape units by first writing random numbers in random length records on all tapes under test and then reading these records back and comparing them with the numbers written. An attempt is made to tabulate and output all useful information concerning the errors made, if any, the mode of operation of each unit, and the number of passes over the tape.

STORAGE: The program occupies from location 40g to 1776g. In a 2K machine the next 1023 words are used as a record buffer area. If the computer has a 4K memory the next 2047 words are used. If the memory is 6K or larger the next 4095 words are used.

TIMING: The program requires approximately 20 minutes to write or read a full reel (2400 feet) of tape.

USE:

- 1.0 LOADING
Place tape in reader and FILL. When loading is complete the light on the typewriter will light if no loading error occurred.
- 2.0 KEYBOARD CONTROL
When the keyboard light is on, the operator has control over the program. By actuating various keys he may set the test parameters, inspect results or start the exerciser test running.
- 2.1 REGAINING KEYBOARD CONTROL
Control may be returned to the keyboard mode at any time by moving the RUN-IDLE-STEP switch to IDLE, pressing the START button, and moving the switch first to STEP then to RUN.

USE: (cont.) 3.0 CONTROL FUNCTIONS

The following list contains the call letters for the various functions which the program will perform. These may be typed anytime the typewriter light is lit.

3.1 SELECT UNITS, "U"

The units to be exercised are selected by first typing the letter "U" followed by the several unit numbers and finally a carriage return. After the last unit number is entered a carriage return must be given to terminate the unit select operation.

3.2 SET STARTING RANDOM NUMBER, "N"

The initial random number is set by first typing the octal number desired (up to 8 digits) and then the letter N. The number being typed can be set to zero by typing a carriage return.

3.3 SET MAXIMUM FILE LENGTH, "M"

The maximum number of records in the test file is set by typing the desired number of records in octal followed by the letter M. If the entire 2400 foot reel is to be written a maximum count of 10000₈ or greater should be sufficient.

3.4 MODE SELECT

The recording mode, either BCD or Binary is selected by typing the appropriate letter.

3.4.1 Select Binary Mode, "B"

Typing the letter B will cause the appropriate EOM instructions to be converted to the binary mode of operation.

3.4.2 Select BCD Mode, "D"

Typing the letter D will cause the EOM instructions to be set for BCD operation.

3.5 SELECT OUTPUT MEDIA

The output of the various messages and counters during the operation of the program can be on either the on-line typewriter or on paper tape for off-line listing. This is controlled by typing the appropriate letter before starting.

USE: (cont.) 3.5.1 Select Typewriter Output, "T"

The typewriter is selected by typing the letter T.

3.5.2 Select Punch Output, "P"

The punch is selected by typing the letter P.

3.6 INITIATE TAPE OPERATION

After the appropriate parameters have been set the tape exercise operation may be initiated. There are three ways in which this may be done. If nothing has been recorded then the exercise must be begun with a START WRITE. However, once a file of information is written on tape and the program is stopped the other two starts can be used.

3.6.1 Start Write, "S"

To begin the exercise operation, type the letter S. The program will rewind all units and start to write a random number test file on the selected units.

3.6.2 Continue Operation, "C"

Once the exercise operation has been stopped with Breakpoint 1 (see section 4.1) it can be resumed from the point at which it was stopped by typing the letter C.

3.6.3 Restart Read, "R"

If during a read pass the program is stopped and the operator would like to reread the file from the beginning he can type the letter R to restart the read pass.

3.7 OUTPUT OPERATIONAL STATUS, "O"

The operator can inspect the status of the operation at anytime by stopping the program with Breakpoint 1 (see section 4.1) and typing the letter O. The program will then type out the status of the exercise operation as follows:

3.7.1 Type of Pass

It types READ or WRITE depending on the type of pass in progress.

3.7.2 Mode of Operation

It then types the mode of operation, either BINARY or BCD.

USE: (cont.) 3.7.3 Density and Unit

The density setting and UNIT NO. of the tape unit currently being addressed are typed. If this unit should not be in automatic the program cannot ascertain its density setting so it will type ***.

3.7.4 Program Counters

After this information the program will type a table of 17 counters each identified by a three or four character symbol. These symbols and their definitions follow:

| | |
|------|---|
| MRC | Maximum Record Count. This is the octal number entered with the M key at the start of the exercise operation. |
| WRC | Write Record Count. If in a write pass this indicates the number of records written. In a read pass it indicates the total number written in the previous write pass. |
| RRC | Read Record Count. This indicates the number of records read during a read pass. |
| WPC | Write Pass Count. The number of write passes completed. |
| RPC | Read Pass Count. The number of read passes completed. |
| WEC | Write Error Count. The number of write errors that have occurred. |
| RWEC | Rewrite Error Count. This number of rewrite errors. |
| PREC | Permanent Read Error Count. The records that were read bad 10 times. |
| CPEC | Character Parity Error Count. The number of character parity errors that have occurred since the start of the exercise. |
| LPEC | Longitudinal Parity Error Count. The number of longitudinal parity errors that have occurred. For each read try only one character or longitudinal parity can be counted and character parity has priority. |

USE: (cont.) WCEC Word Count Error Counts. The number of word count errors that have occurred. A word count error occurs if the record read is longer or shorter than the record expected.

| | | |
|--|---|---|
| CH1 CH2 CH3 CH4 CH5 CH6 | } | Errors in Channels 1-6. Channel 1 is the most significant bit, channel 6 the least. These counters are also output whenever a read error occurs if Breakpoint 2 is RESET. After a read error output they are cleared. |
|--|---|---|

4.0 BREAKPOINT SWITCHES

The four Breakpoint switches are used to change the status of the program while it is running. These functions are as follows:

4.1 BREAKPOINT 1

RESET: Normal

SET: Stop operation. After almost every tape operation there is a STOP point. If Breakpoint 1 is set the program will mark its place and return to the keyboard control mode. Operation can be continued by typing the letter C.

4.2 BREAKPOINT 2

RESET: Output counters and messages whenever the normal output situation occurs.

SET: Skip the output of messages and counters. This will inhibit all output except the OUT OF SYNC message and the FILE PROTECT ON message.

4.3 BREAKPOINT 3

RESET: At the end of a read pass go on to another write with new random numbers.

SET: At the end of a read pass go back and reread the same file again.

4.4 BREAKPOINT 4

RESET: Run without halts.

SET: Halt on a write error or at the end of a read pass. Clearing these halts will allow the program to continue.

USE: (cont.) 5.0 MESSAGES

The program will type or punch status messages at various times in the operation of the exercise. These are described below:

5.1 END OF PASS

At the end of a write or read pass the output will be either WRITE or READ, PASS DONE. This is followed by a carriage return and the following two lines:

```
WRITES    READS    WRITE ERR    REWRITES    BAD    READS
aaaaaaaaa bbbbbbbb cccccccc dddddddd eeeeeeee
```

where the a's represent the number of write passes in octal, the b's the number of read passes, the c's the number of write errors which have occurred, the d's the number rewrite errors, and the e's the number of records which were read erroneously 10 times.

5.2 REWRITE ERROR

If a write error is detected the program erases backward over the record and attempts to rewrite it. If this second attempt is also in error the program outputs the following counter titles:

```
WRITE PASS    RECORD NO.    WRITE ERRS    REWRITE ERRS
```

This is followed on the same line by the mode of operation (Binary or BCD) the density and the unit number. On the next line below the appropriate title it outputs the write pass count, the write record number count, the write error count and the rewrite error count. All counts are in octal.

5.3 READ ERROR

If a read error occurs, the program rereads the record nine more times and then outputs the read pass, record number, mode, density, and unit number. This is followed by a carriage return, the message, READ ERROR, another carriage return and then nine, eight-octal-digit counters which represent the following quantities (from left to right): character parity error count, longitudinal parity error count, word count, error count, errors in channel 1, channel 2, etc., to channel 6. On the next line the program outputs a good or bad message for each of the 10 reads. This consists of the letter G if the read was correct or B if the read was incorrect.

USE: (cont.)

For example:

B G G G B G G G G G

Indicates that the first and fifth reads were bad and all others were good.

5.4 READ PASS OUT OF SYNC

The first word of every record is the number of records preceding it on the tape. When each record is read, the program compares this first word with the read record count. If they disagree the program backspaces and rereads the record a second time, if they still disagree then the difference between them is computed and the program spaces over as many records as necessary to position itself in front of the correct record. If the first word of this record does not agree with the read record count after two attempts the program ends the read pass and outputs the following. As in a read error it outputs the read pass count, read record number, mode, density and unit number. This is followed by this message:

```

READ PASS ABORT, OUT OF SYNC.
    aaaaaaaaaa      bbbbbbbb

```

where the a's represent the first word of the first record read that did not agree with the read record count, and the b's represent the first word of the record read after spacing to what should have been the correct record. The program then goes to the end of read pass section where the end of pass output will be produced and from there on to another write or reread pass.

If a tape mark or the load point was encountered when spacing, the program terminates the read pass and outputs TAPE MARK before the other outputs. If it was the load point which was encountered it also outputs LOAD POINT. In either case the two words a and b will be the same since only one record was read.

5.5 FILE PROTECT ON

Before the program attempts to write on a tape it tests the file protect for that unit. If the file protect should be on, the program outputs: FILE PROTECT ON (Mode) (Density) UNIT NO. n. and returns to the keyboard mode.

METHOD: 1.0 WRITING

At the start of the write pass all units are rewound. The program then sets the tape control table for the lowest numbered unit and waits for it to be ready. As soon as this unit is ready a check is made to see if the tape is at

METHOD: (cont.) the loadpoint. If it is not, another rewind is given and the program waits until it is ready and at the load point. A three inch section of tape is erased before the first random number record is written. After writing this record on the first unit the control table is set to the next higher numbered unit and the record is written again. This continues until a record has been written on all units under test. The program then generates a new record of random numbers and starts writing this on all units.

1.1 WRITE ERROR

If a write error occurs the program erases backward to the front of this record and attempts to rewrite it. If this second attempt is also in error then the program outputs the rewrite error message. It then erases backward over the record again, erases it forward and attempts to write the record again on a new section of tape. An error here is considered a new write error and the process continues until a correct write is made.

1.2 END OF PASS

The write pass is concluded if one of two conditions occurs: Either the write record count reaches the maximum record count or an end of reel is encountered on any tape under test. When one of these occurs the program writes an end of file on all units and rewinds them. It then outputs the end of pass message and proceeds to the read pass.

2.0 READING

A read pass is similar to a write except that the program reads each record into memory and compares it with the random numbers which it regenerates for each read. The first record must be read starting from the load point. This insures that the tape is always positioned properly for the start of the pass.

2.1 READ ERRORS

When a read error occurs the program will always reread the record nine more times for a total of ten attempts regardless of whether or not a subsequent read was correct. It then outputs the results of these reads. Several conditions can cause a read error.

2.1.1 Character Parity Errors

The program counts a character parity error as any buffer error which occurs before the gap is reached.

METHOD: (cont.)

2.1.2 Longitudinal Parity Error

If no character parity errors have occurred before the gap is reached and the buffer error is on after the gap signal is detected, the program counts a longitudinal parity error.

2.1.3 Word Count Error

A word count error is defined as a record which was not of the length expected. The program tests for this in three ways. If more words than expected were read an I1 interrupt will occur because the interlace unit has been counted to zero. The program presets the last two words of the expected record buffer area to zero and checks to see that some information was read into these words. The third test is based on the fact that the program always writes records that consist of a multiple of four characters. Therefore if the buffer contains anything other than zero at the end of the read an error has occurred.

2.2 READ SYNCHRONIZATION

When each record is read the first word is compared against the program record count. If they disagree it means that the program and tape are no longer synchronized. To guard against a read error causing the disagreement, the program backspaces and reads the record again. If they still disagree then the program computes the number of records to be spaced over in order to reach the desired record and moves to that point. It reads the new record and again checks the first word. If this word disagrees with the record count and a second read attempt does not correct the disagreement then the program aborts the read pass and outputs the appropriate message. If a tape mark or the load point is encountered while spacing to the correct position the pass is aborted without further read attempts.

2.3 END OF FILE

If the program should receive an I2 interrupt before a gap signal is received then a check for end of file is made. If the interrupt was caused by the reading of a tape mark then the read pass is complete and appropriate messages are output. If there is no end of file signal after the I2 then the program assumes that the tape mark detector is not working and terminates the read pass anyway and outputs an END OF FILE READ ERROR message.

METHOD: 3.0 BCD MODE

In the BCD mode random numbers are generated and written the same as in binary. However, on the read pass all non compares between the generated number and the number from tape are checked to see if they are caused by the 12 to 00 conversion. This occurs because both the character 00 and the character 12 will be written on tape as a 12 but this character will always be read into memory as a 00.

SDS 900 SERIES PROGRAM LIBRARY

PROGRAM DESCRIPTION

Page 1 of 7

Catalog No. 299008

IDENTIFICATION: 920 Closed Loop Analog Statistical Test Program

AUTHOR: L. Bergquist, SDS

ACCEPTED: 11 May 1964

COMPUTER CONFIGURATION: Applicable to any SDS 920 computer system with EJ20 Standard Junction Box.

PURPOSE: To compute the mean and standard deviation from closed loop analog measurements for the purpose of determining system accuracy and stability.

PROGRAMMED OPERATORS: DPSS, BID, DSQ

STORAGE: Program allocation 001, 100₈ to 1756₈. Temporary storage 40₈ to 64₈. Data storage 30₈ locations per D/A channel.

TIMING: 1.3 ms/scan/channel.

USE: 1.0 LOADING

The program is in absolute format on a self-loading binary tape. All necessary Programmed Operators and their linkages are contained on the program tape. Use FILL procedure to load the program.

2.0 RESTART

If it is required at any time to restart the program, set the RUN-IDLE-STEP switch to IDLE, press START, and move the switch to STEP and then to RUN.

3.0 SYSTEM PARAMETERS

Following Loading or Restart the program will request the operator to define several system parameters. These include the number of D/A channels, the size of the ADC converter, and the starting multiplexer channel for the first D/A converter. All numerical inputs are in decimal.

USE: (Cont)

3.1 "D/A CHANNELS"

Input the number of D/A channels to be tested.

3.2 "ADC SIZE"

Input the size of the analog to digital converter including the sign.

3.3 "MX CHANNEL"

Input the multiplexer channel number associated with the first digital to analog converter. Each additional digital to analog converter will be input through succeeding multiplexer channels.

4.0 SCAN PARAMETERS

Included in the scan parameters that require operator input are the channel number, number of scans to be performed, and the output limits for the digital to analog converter.

4.1 "SCAN COUNT"

Input the number of scans to be performed for each channel.

4.2 "CHANNEL"

Input the D/A channel to be scanned (0 to N). If all D/A channels are to be scanned simultaneously, input the letter "A" instead of the decimal input,

4.3 "LIMITS"

Input the limits, as decimal fractions, indicating the low and high values to be output to the D/A converters as a step function. If a random function is desired, input the letter "R" instead of the first decimal input. The program will proceed to scan following these inputs.

5.0 SCAN

The scan consists of an accumulation of data obtained from system measurements. System measurements involve output to a D/A converter, selecting the return multiplexer channel, and input from the ~~AD~~ converter. Each successive output for a particular D/A converter uses a different value computed from either a random number generator or a step generator.

USE: (Cont)

The accumulation of data consists of updating sums for mean and standard deviation computation and updating a distribution table. The distribution table represents a record of measurements deviating from their expected in converter counts. The table ranges up to plus or minus 8 converter counts. Those greater than 8 are listed as 8.

Scan will terminate when one of two conditions is attained. Either operator intervention by breakpoint control, or the Scan Count has been reached. Breakpoint control consists of depressing and raising a breakpoint switch.

5.1 Breakpoint #1

If Breakpoint #1 is depressed during Scan or listing, control is transferred to Scan Parameters (4.0).

5.2 Breakpoint #2

If Breakpoint #2 is depressed during Scan or listing, control is transferred to Output Parameters (6.0).

5.3 Scan Limit

When the number of scans have been performed, defined in Scan Parameters, Scan will terminate and control transfer^{^ will be} to Output Parameters (6.0).

6.0 OUTPUT PARAMETERS

Following Scan, the program will request the operator to define two output parameters before listing the data. These are the format and the channel number to be output.

6.1 "CHANNEL"

Input the D/A channel to be output (0 to N). If there is no input, the last channel or channels previously scanned will be listed.

6.2 "FORMAT"

Input the character "M" or "D" specifying the type of listing desired (see Table II for examples). If no input is made, the previous format is assumed.

USE: (Cont)

6.2.1 General Format, Input "D"

The general format listing consists of the channel number, the number of scans performed, the maximum and minimum measurements made from the expected measurement, the mean bias (mean measurement from the expected), the standard deviation about the mean bias, and a distribution table representing deviation of measurements in ADC converter counts about the expected measurement (D/A output value).

6.2.2 Abbreviated Format, Input "M"

Only the channel number, mean bias, and standard deviation are listed.

METHOD:

The mean bias and standard deviation are computed in the following manner.

For all $X_i = (\text{ADC value})_i - (\text{D/A value})_i$

$$\text{Mean bias} = \frac{1}{n} \sum_{i=1}^n X_i = \delta$$

$$\text{Standard deviation} = \left[\frac{1}{n} \sum_{i=1}^n (X_i)^2 - (\delta)^2 \right]^{1/2}$$

TABLE I

CLOSED LOOP ANALOG STATISTICAL TEST PROGRAM

| COMPUTER OUTPUT | INPUT RANGE | REMARKS |
|----------------------|---------------------------|--|
| I. A. "D/A CHANNELS" | 1. 1 to N | Follows Loading or Restart. Specify the total number of D/A converters under test. |
| I. B. "ADC SIZE" | 1. 7 to 14 | Specify the size of the Analog to Digital converter including the sign. |
| I. C. "MX CHANNEL" | 1. 0 to N | Specify the multiplexer channel associated with the first D/A channel. |
| II. A. "SCAN COUNT" | 1. 1 to N | Follows data listing or Breakpoint #1. Specify the number of scans to be performed for each channel. |
| | 2. no entry | Assume last specified scan count. |
| II. B. "CHANNEL" | 1. 0 to N | Perform test on specified D/A channel only. |
| | 2. A | Perform test on all D/A channels (I. A.). |
| | 3. no entry | Assume last specified channel or channels (II. A.). |
| II. C. "LIMITS" | 1.a. -.99999 to .99999 | Input lower limit of 'ramp' function. |
| | 1.b. -.99999 to .99999 | Input upper limit of 'ramp' function. |
| | 2. R | Perform 'random' function over entire D/A range |
| | 3. no entry | Assume last output function and limits. |
| | | |

TABLE I (Cont)

| COMPUTER OUTPUT | INPUT RANGE | REMARKS |
|-------------------|-------------|--|
| III. A. "CHANNEL" | 1. 0 to N | Output the data for the specified D/A channel |
| | 2. A | Output data for all D/A channels (I.A.) |
| | 3. no entry | Output data for channel or channels specified under II. B. |
| III. B. "FORMAT" | 1. M | Output the channel number, mean, and standard deviation (see Table II). |
| | 2. D | Output the channel number, total number of scans, maximum and minimum measurements, mean measurement, standard deviation about the mean, and a distribution table (see Table III.) |
| | 3. no entry | Assume previous specified format. |

TABLE III

1. 'M' (Typical for simultaneous 3 channel scan.)

| CHANNEL | MEAN | STD DEVIATION |
|---------|------|---------------|
| 0 | 1.56 | .49 |
| 1 | .64 | 1.02 |
| 2 | .20 | .15 |

2. 'D' (Typical for single channel scan)

| | |
